

# Neural Networks: Convolutional Nets, Regularization, Data augmentation, Dropout

Machine Learning Course - CS-433

Nov 6, 2024

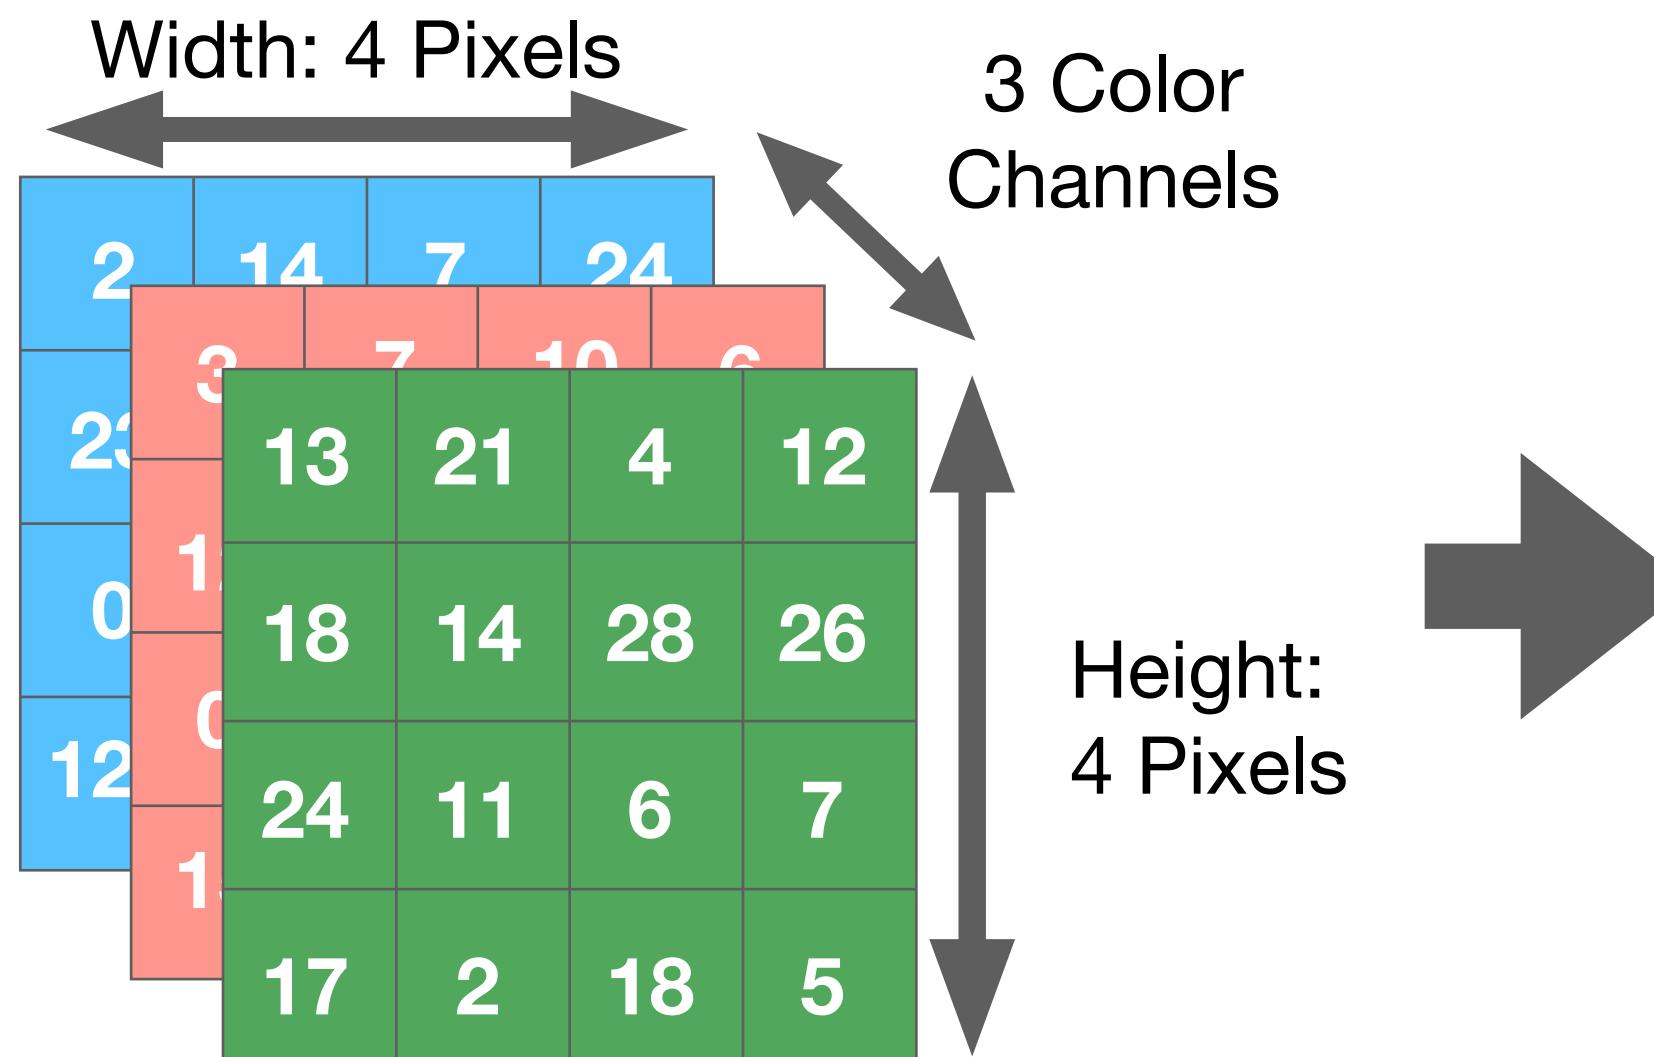

Nicolas Flammarion

# Convolutional Networks

# Fully connected NNs have many parameters and do not capture spatial dependencies

- Fully connected NNs have  $O(K^2L)$  parameters: training requires a lot of data

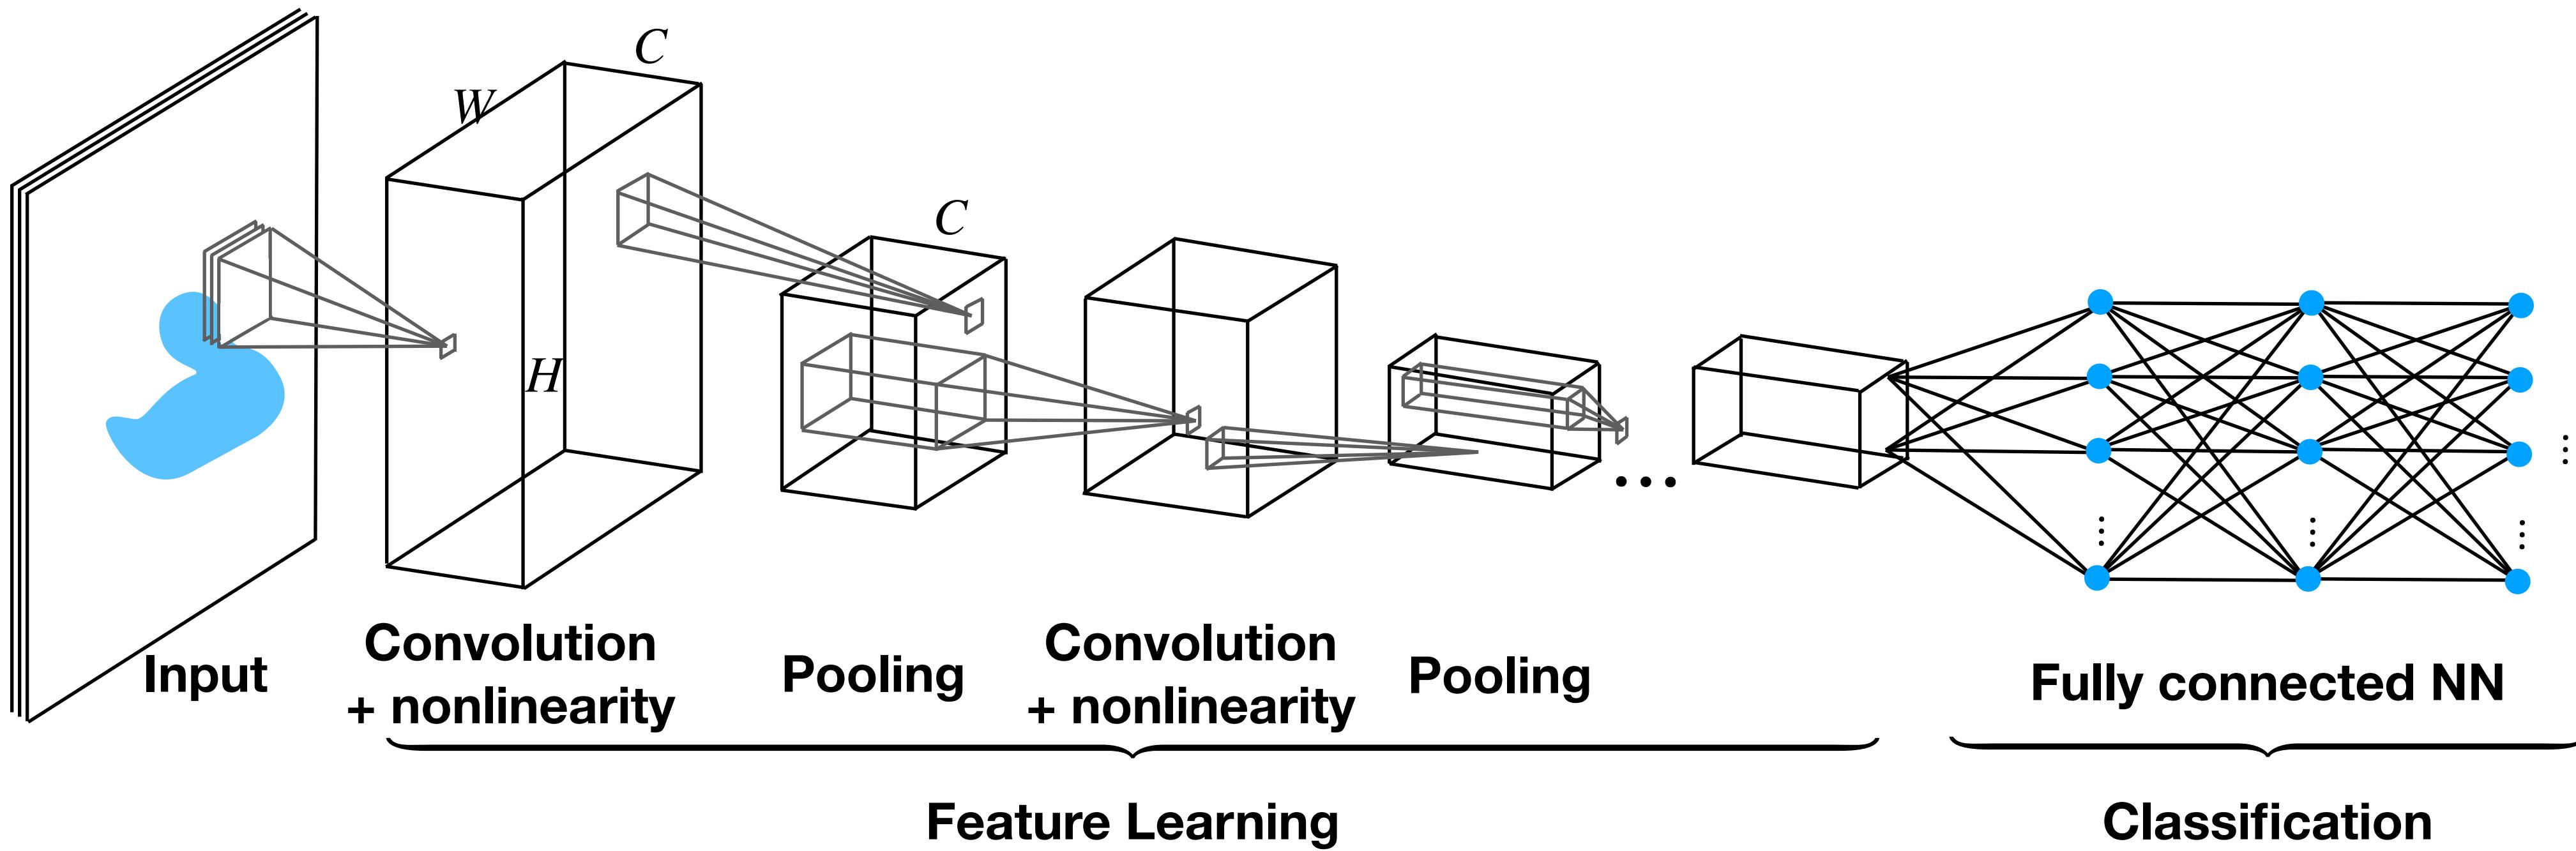

ImageNet Dimension:  
 $256 \times 256 \times 3 \sim 2 \cdot 10^5$

- Fully connected neural networks interpret an image as a flattened vector, disregarding the original spatial dependencies

Flattening of a  $3 \times 3$  picture into a  $1 \times 9$  vector

# Convolutional NNs: General Structure

- Convolutional networks consist of **sparsely connected convolutional layers** in place of fully-connected linear layers
- **Pooling layers** perform spatial downsampling (typically reducing the dimensions from  $H \times W$  to  $H/2 \times W/2$ )
- A fully-connected network at the end performs classification based on the extracted features

# Convolution

For a filter  $f$  of size  $K$  and a stride  $S$ :

$$x_{n,m}^{(1)} = \sum_{k,l=0}^{K-1} f_{k,l} \cdot x_{nS+k, mS+l}^{(0)}$$

- For example,  $K = 3, S = 1$

$$x_{0,0}^{(1)} = \sum_{k=0}^2 \sum_{l=0}^2 f_{k,l} \cdot x_{0+k, 0+l}^{(0)}$$

$$x_{0,1}^{(1)} = \sum_{k=0}^2 \sum_{l=0}^2 f_{k,l} \cdot x_{0+k, 1+l}^{(0)}$$

$\vdots$  **Weight sharing**

- Filter  $f$  represents the learnable weights, analogous to the weights  $W$  in an MLP
- We use the same filter at every position - **weight sharing**

1 $\times 0$	0 $\times 1$	1 $\times 0$	1	0
1 $\times 1$	1 $\times 1$	0 $\times 0$	1	1
0 $\times 0$	0 $\times 0$	1 $\times 1$	1	0
0	1	1	0	0
1	1	1	0	1

Convolved Feature with stride  $S = 1$

# Convolution

$$x_{n,m}^{(1)} = \sum_{k,l=0}^{K-1} f_{k,l} \cdot x_{nS+k, mS+l}^{(0)}$$

- **Local connectivity** -  $x_{n,m}^{(1)}$  only depends on the value of  $x^{(0)}$  close to  $(nS, mS)$  for small  $K$
- **Translation equivariance** - a shifted input results in a shifted output

1 ×0	0 ×1	1 ×0	1	0
1 ×1	1	0 ×0	1	1
0 ×0	0 ×0	1 ×1	1	0
0	1	1	0	0
1	1	1	0	1

0	1	0
1	1	0
0	0	1

Filter  $f$

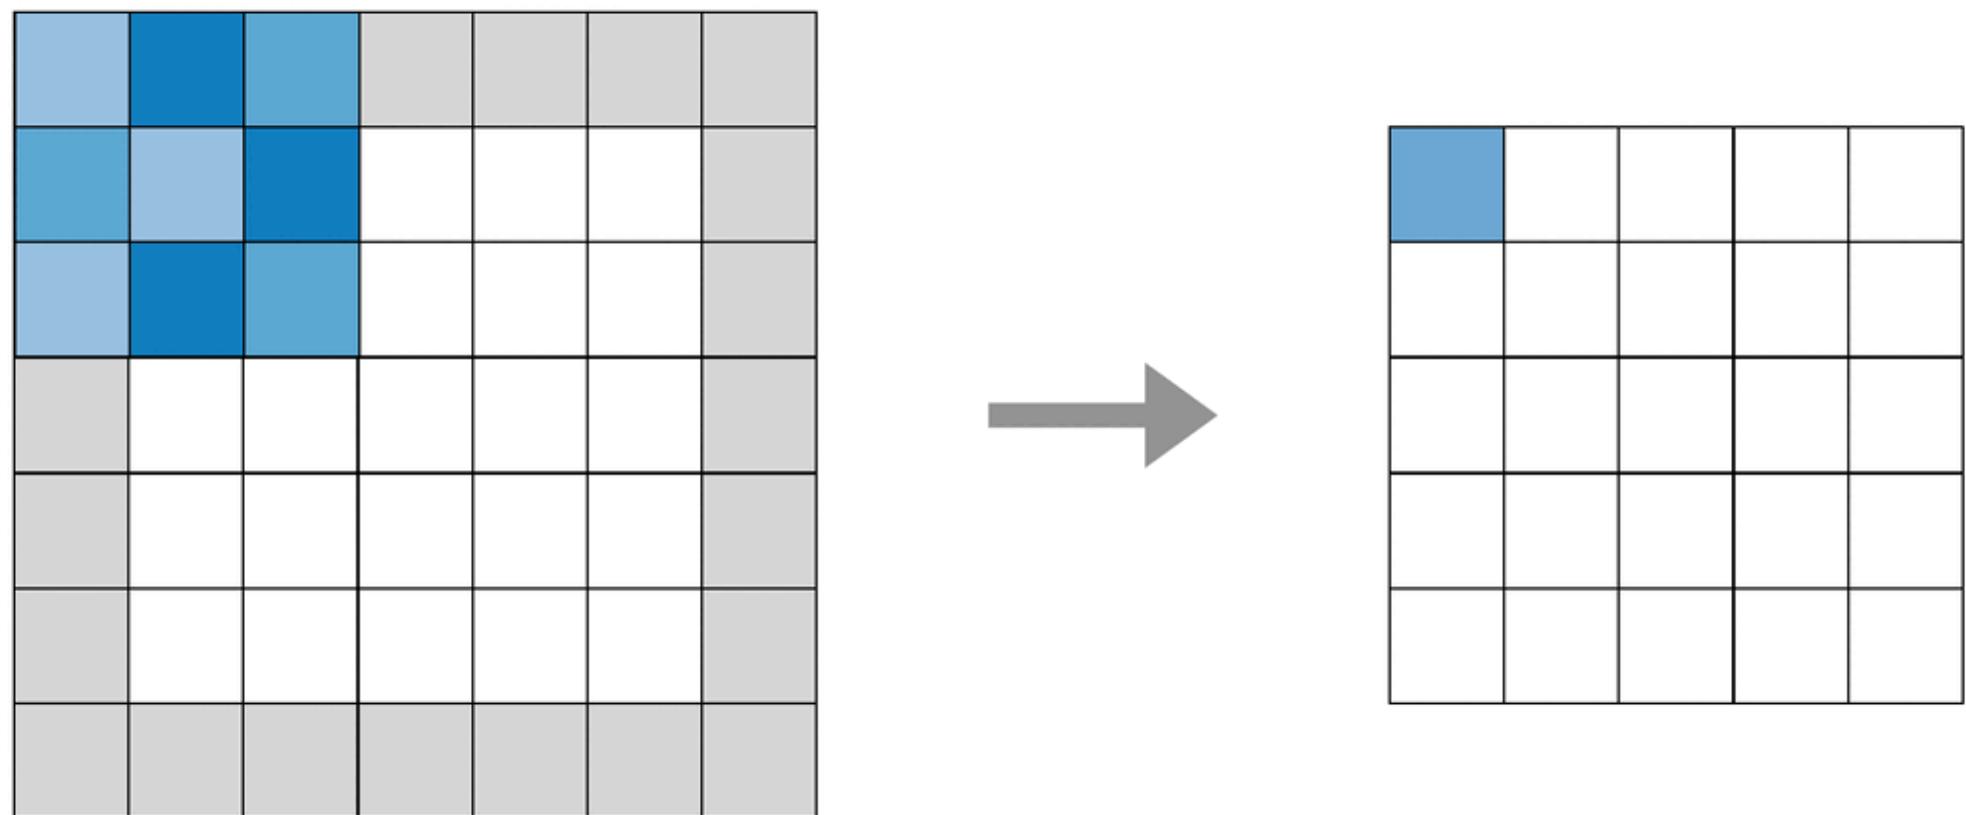

3		

Convolved Feature with stride  $S = 1$

→ Convolution requires fewer parameters which are universal across different locations

# Handling of borders

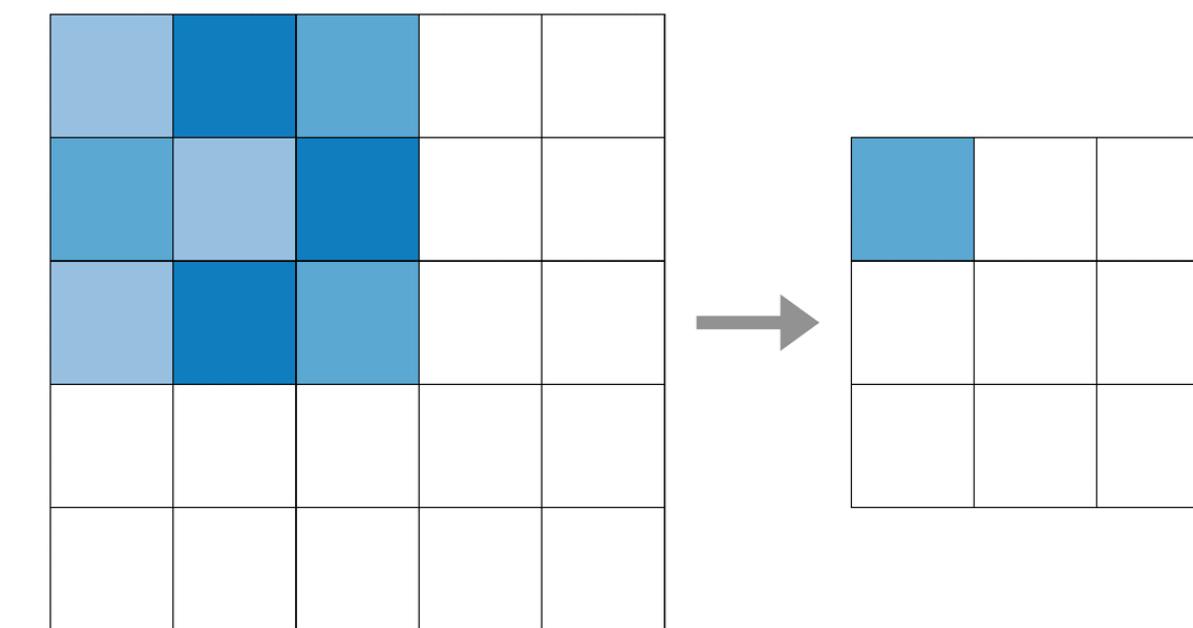

Zero padding:

Add zeros to each side of the input's boundaries

- The convolved feature has the same dimension as the input

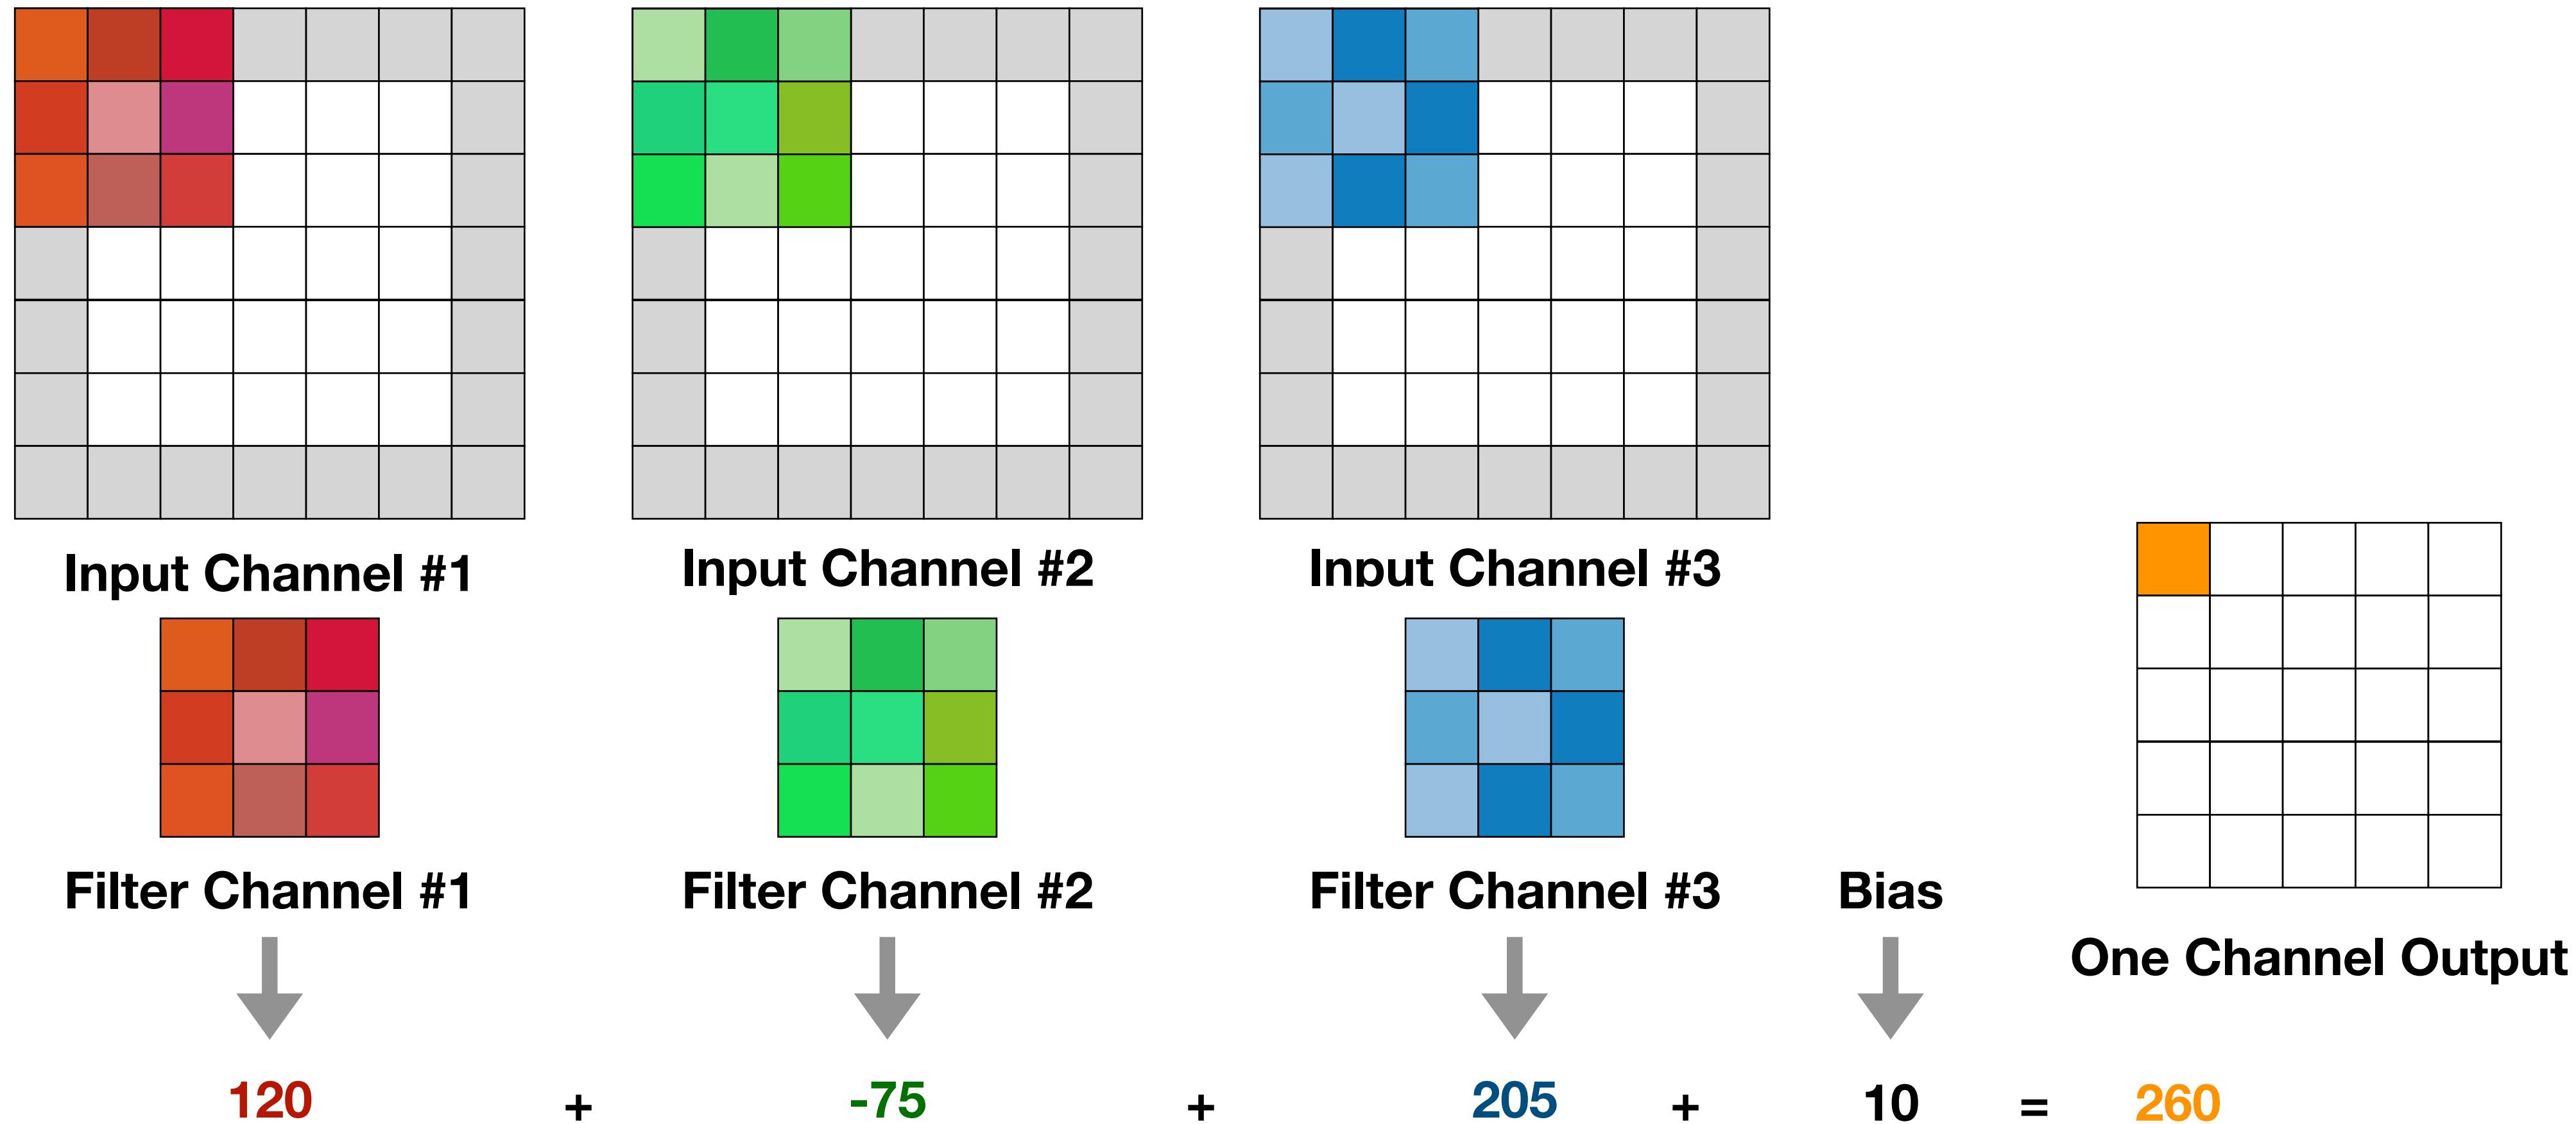

Valid padding:

Perform the convolution only where the entire filter fits inside the original data

- The convolved feature has smaller dimensions than the input

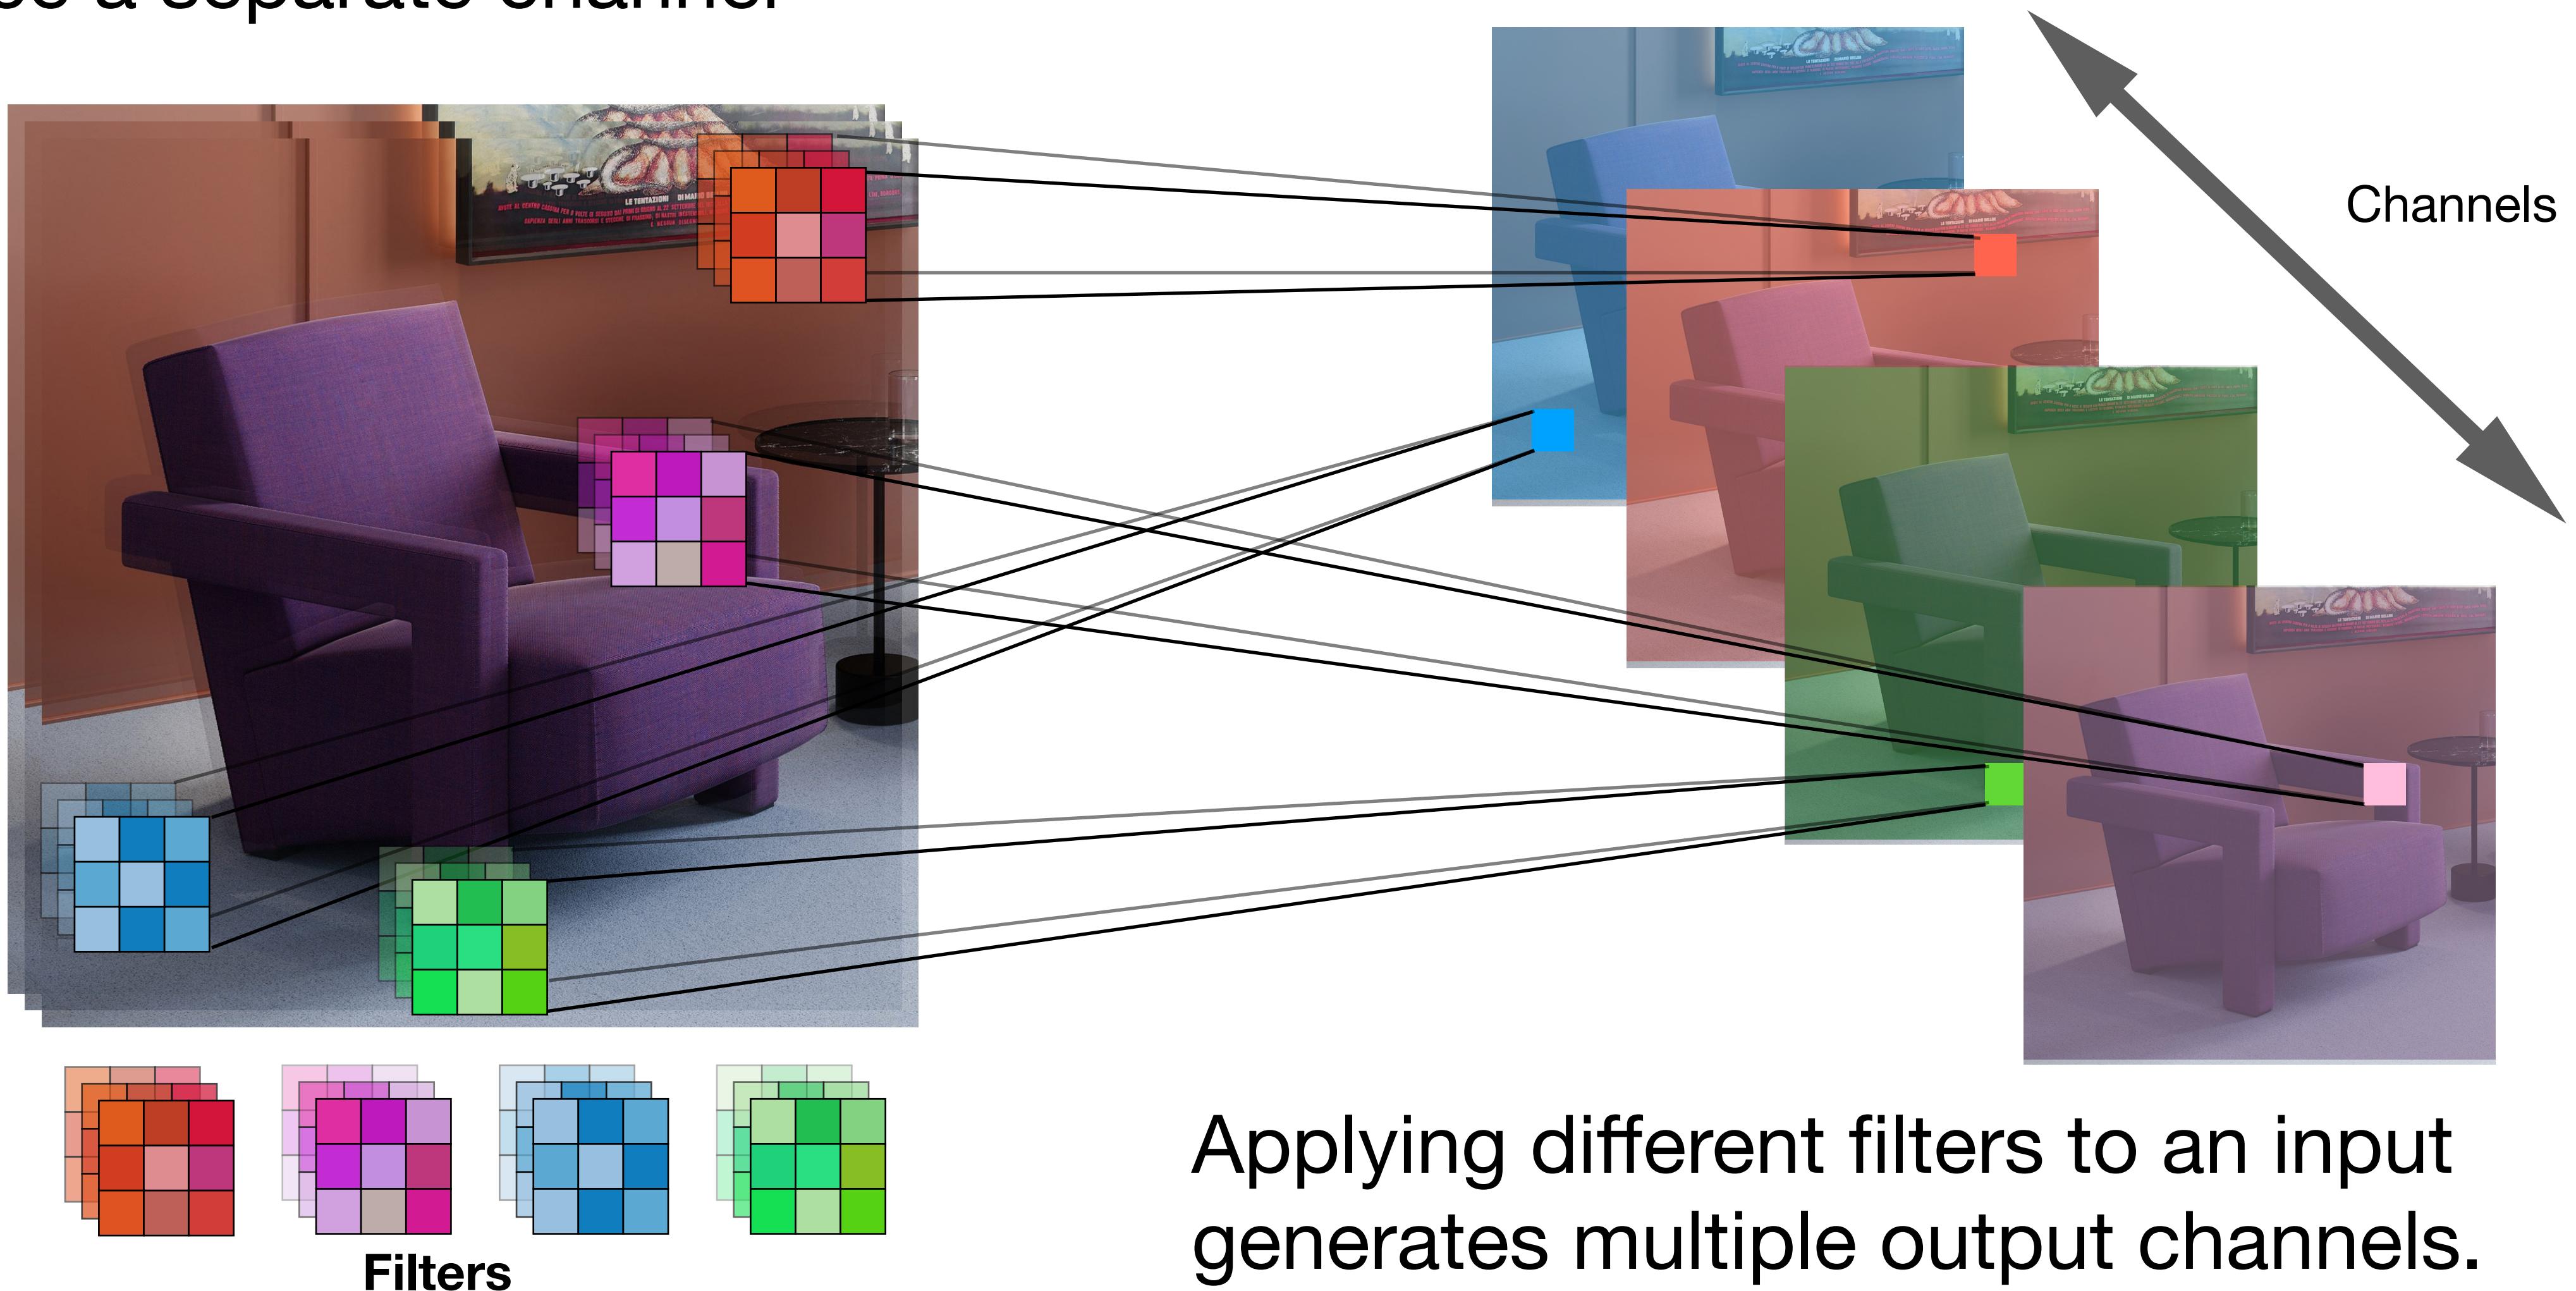

# Filter for Multi-Channel Convolution

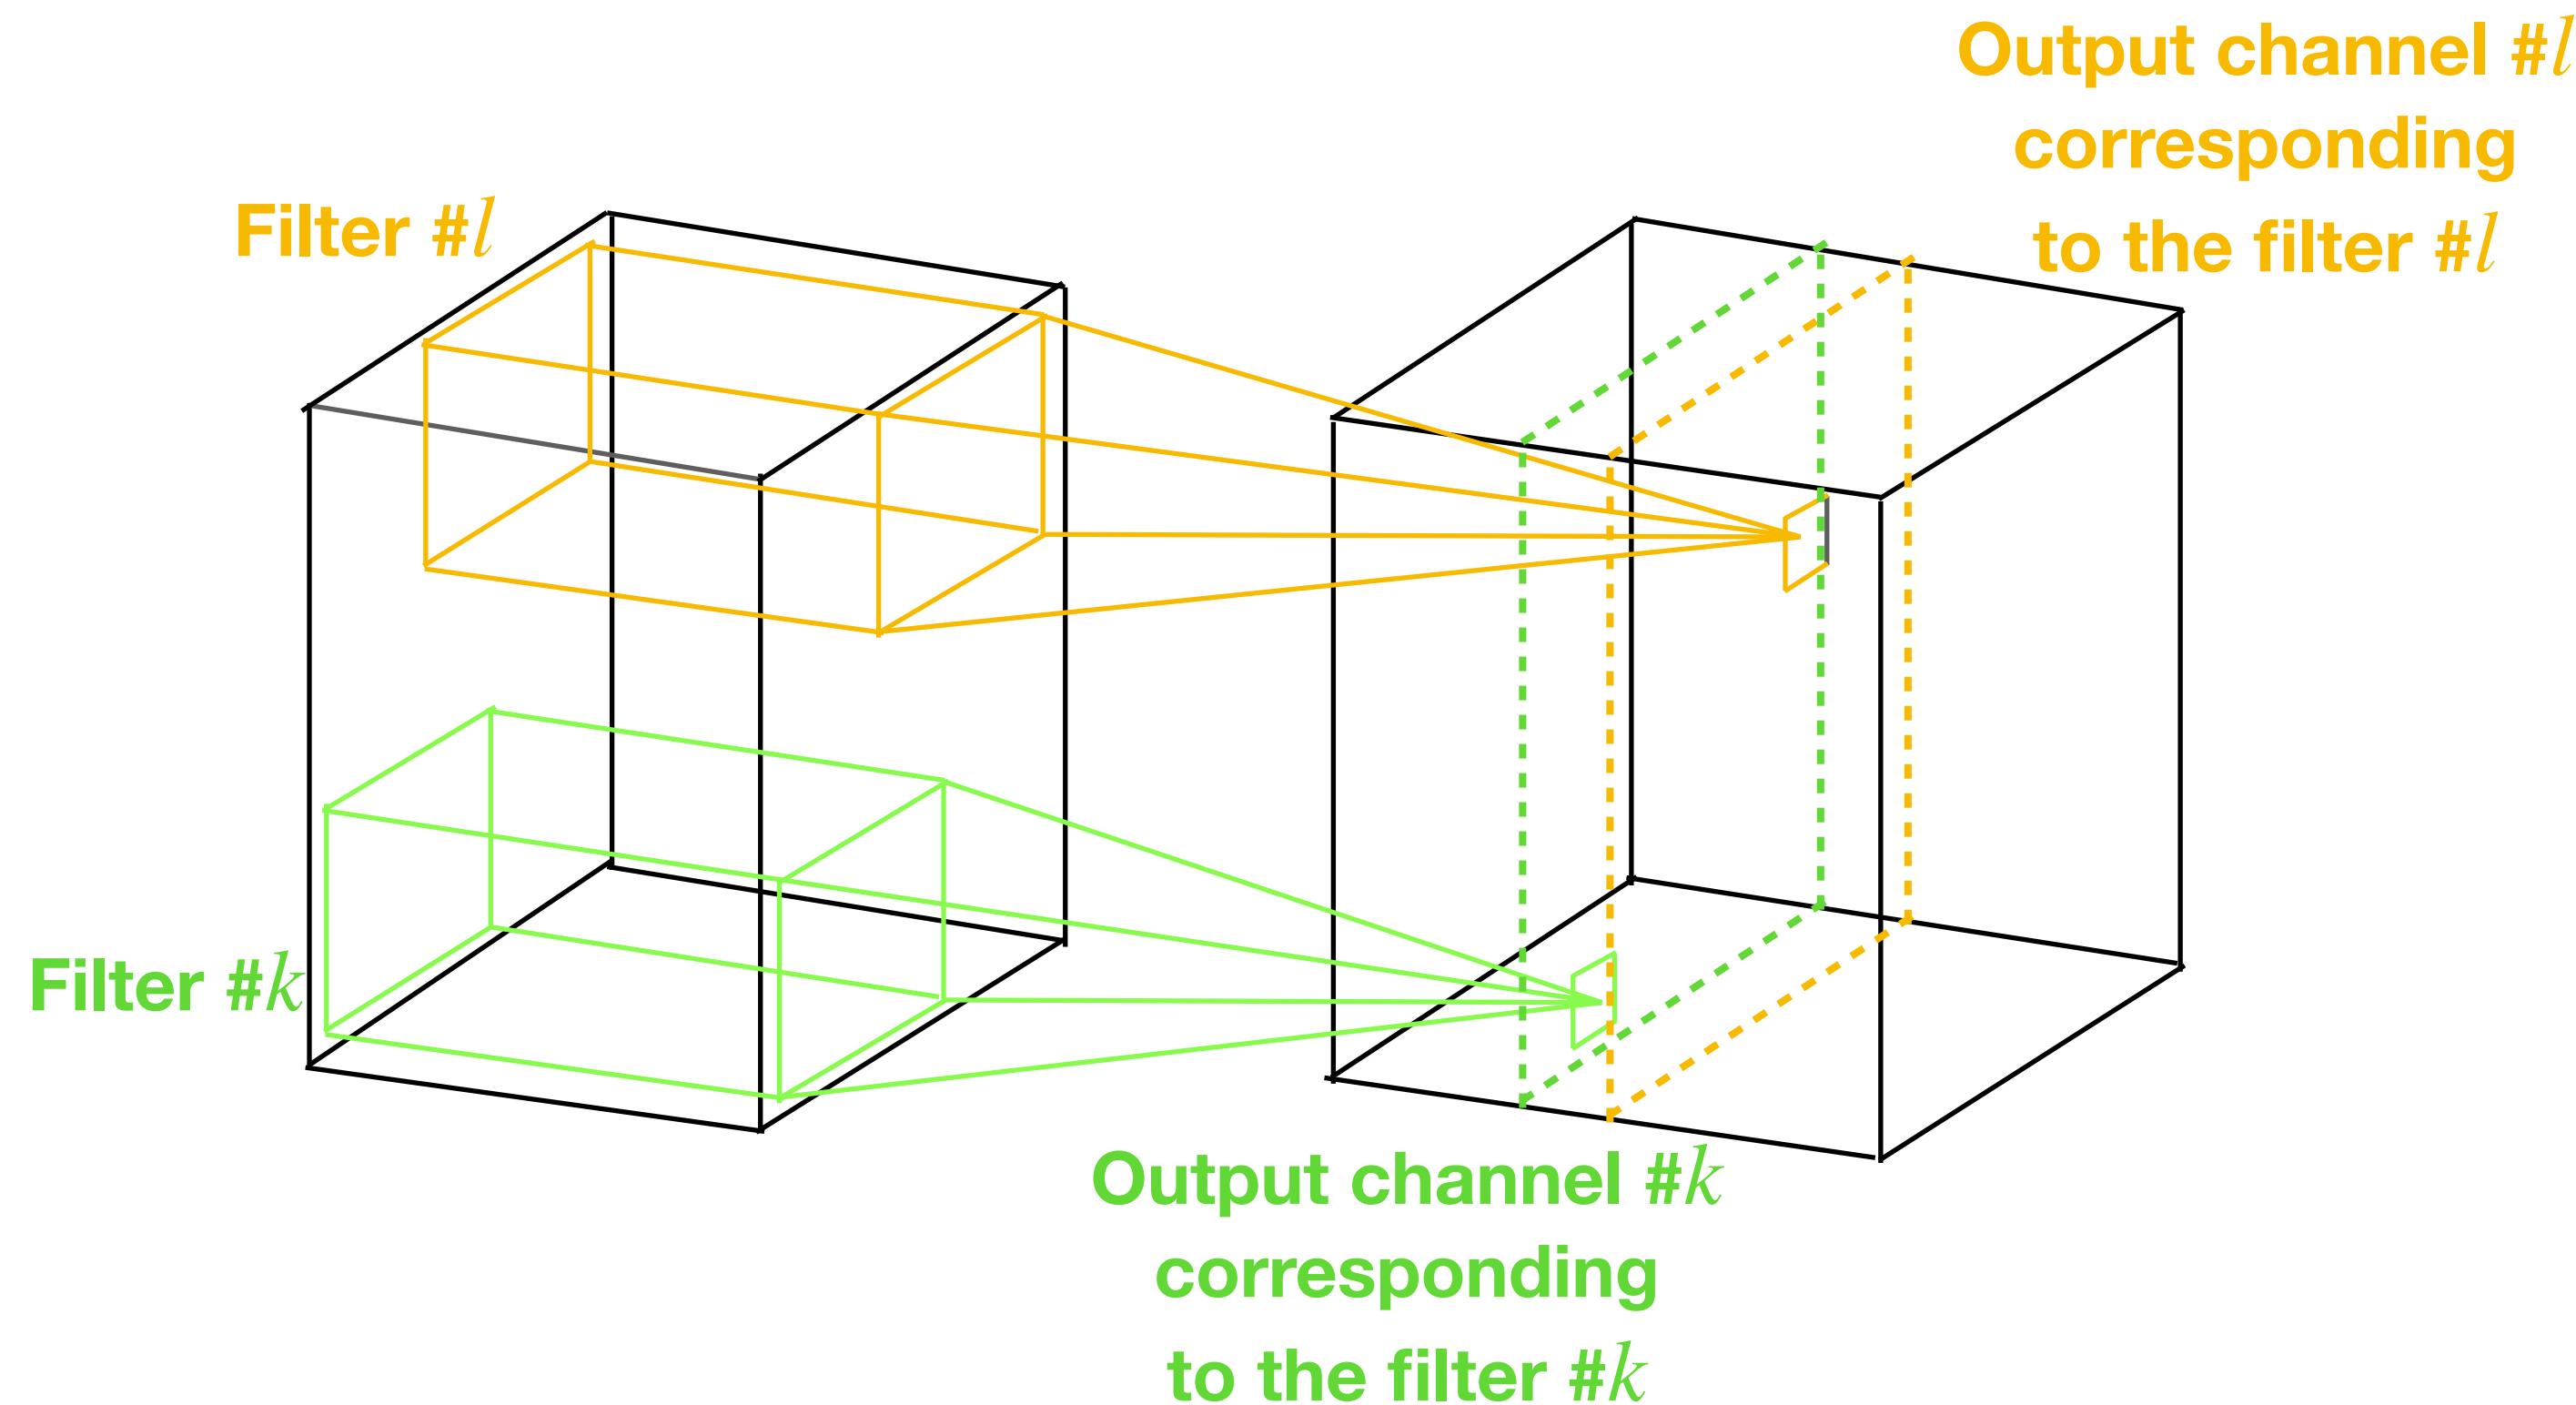

- For multi-channel inputs, the filter has the same number of channels as the input
- The filter channels and the bias are the learnable parameters of the filter

# Multi-Channel Output from Multiple Filters

It is common to use multiple filters. Each filter processes the input to produce a separate channel

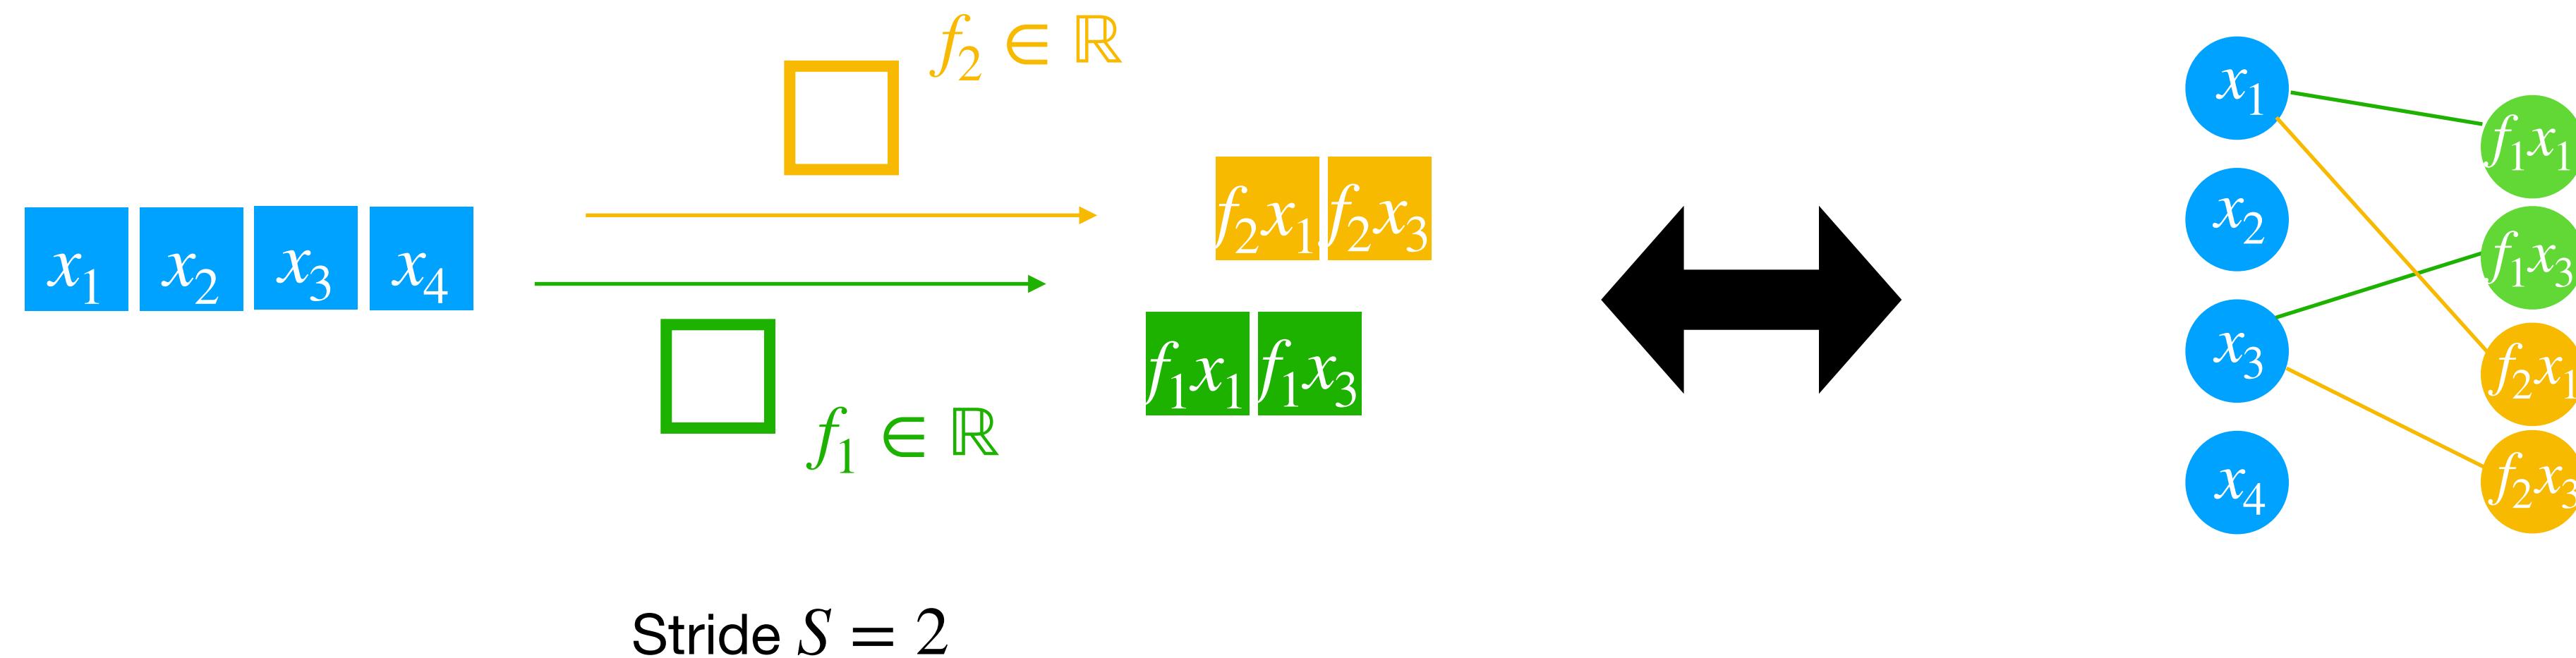

# Convolutional Layer

- A convolutional layer is composed of multiple filters
- Each output channel corresponds to its own independent filter
- Hyper-parameters of the convolutional layer: size, padding, stride

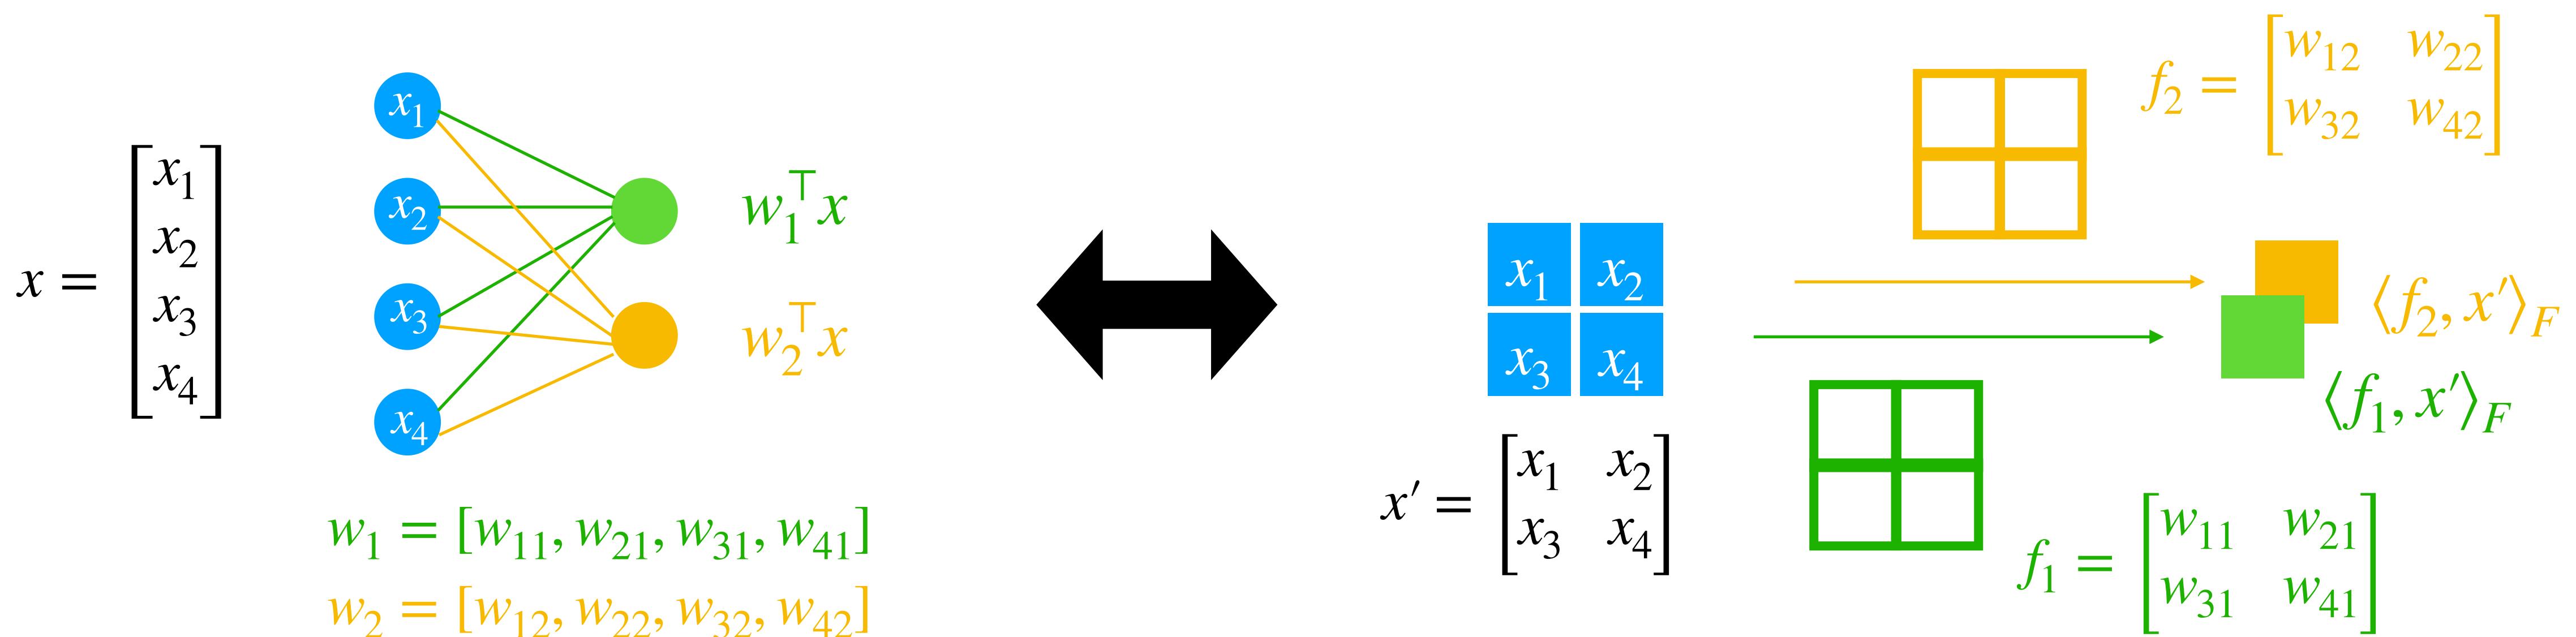

# Equivalence between Convolution and Fully Connected Layers

- For any Convolution layer there is an Fully Connected (FC) layer that implements the same forward function:
  - The FC weight matrix would be a large matrix that is mostly zero except for at certain blocks (due to local connectivity) where the weights in many of the blocks are equal (weight sharing).

# Equivalence between Convolution and Fully Connected Layers

- For any Convolution layer there is an Fully Connected (FC) layer that implements the same forward function:
  - The FC weight matrix would be a large matrix that is mostly zero except for at certain blocks (due to local connectivity) where the weights in many of the blocks are equal (weight sharing).
- Conversely, any FC layer can be converted to a Convolution layer

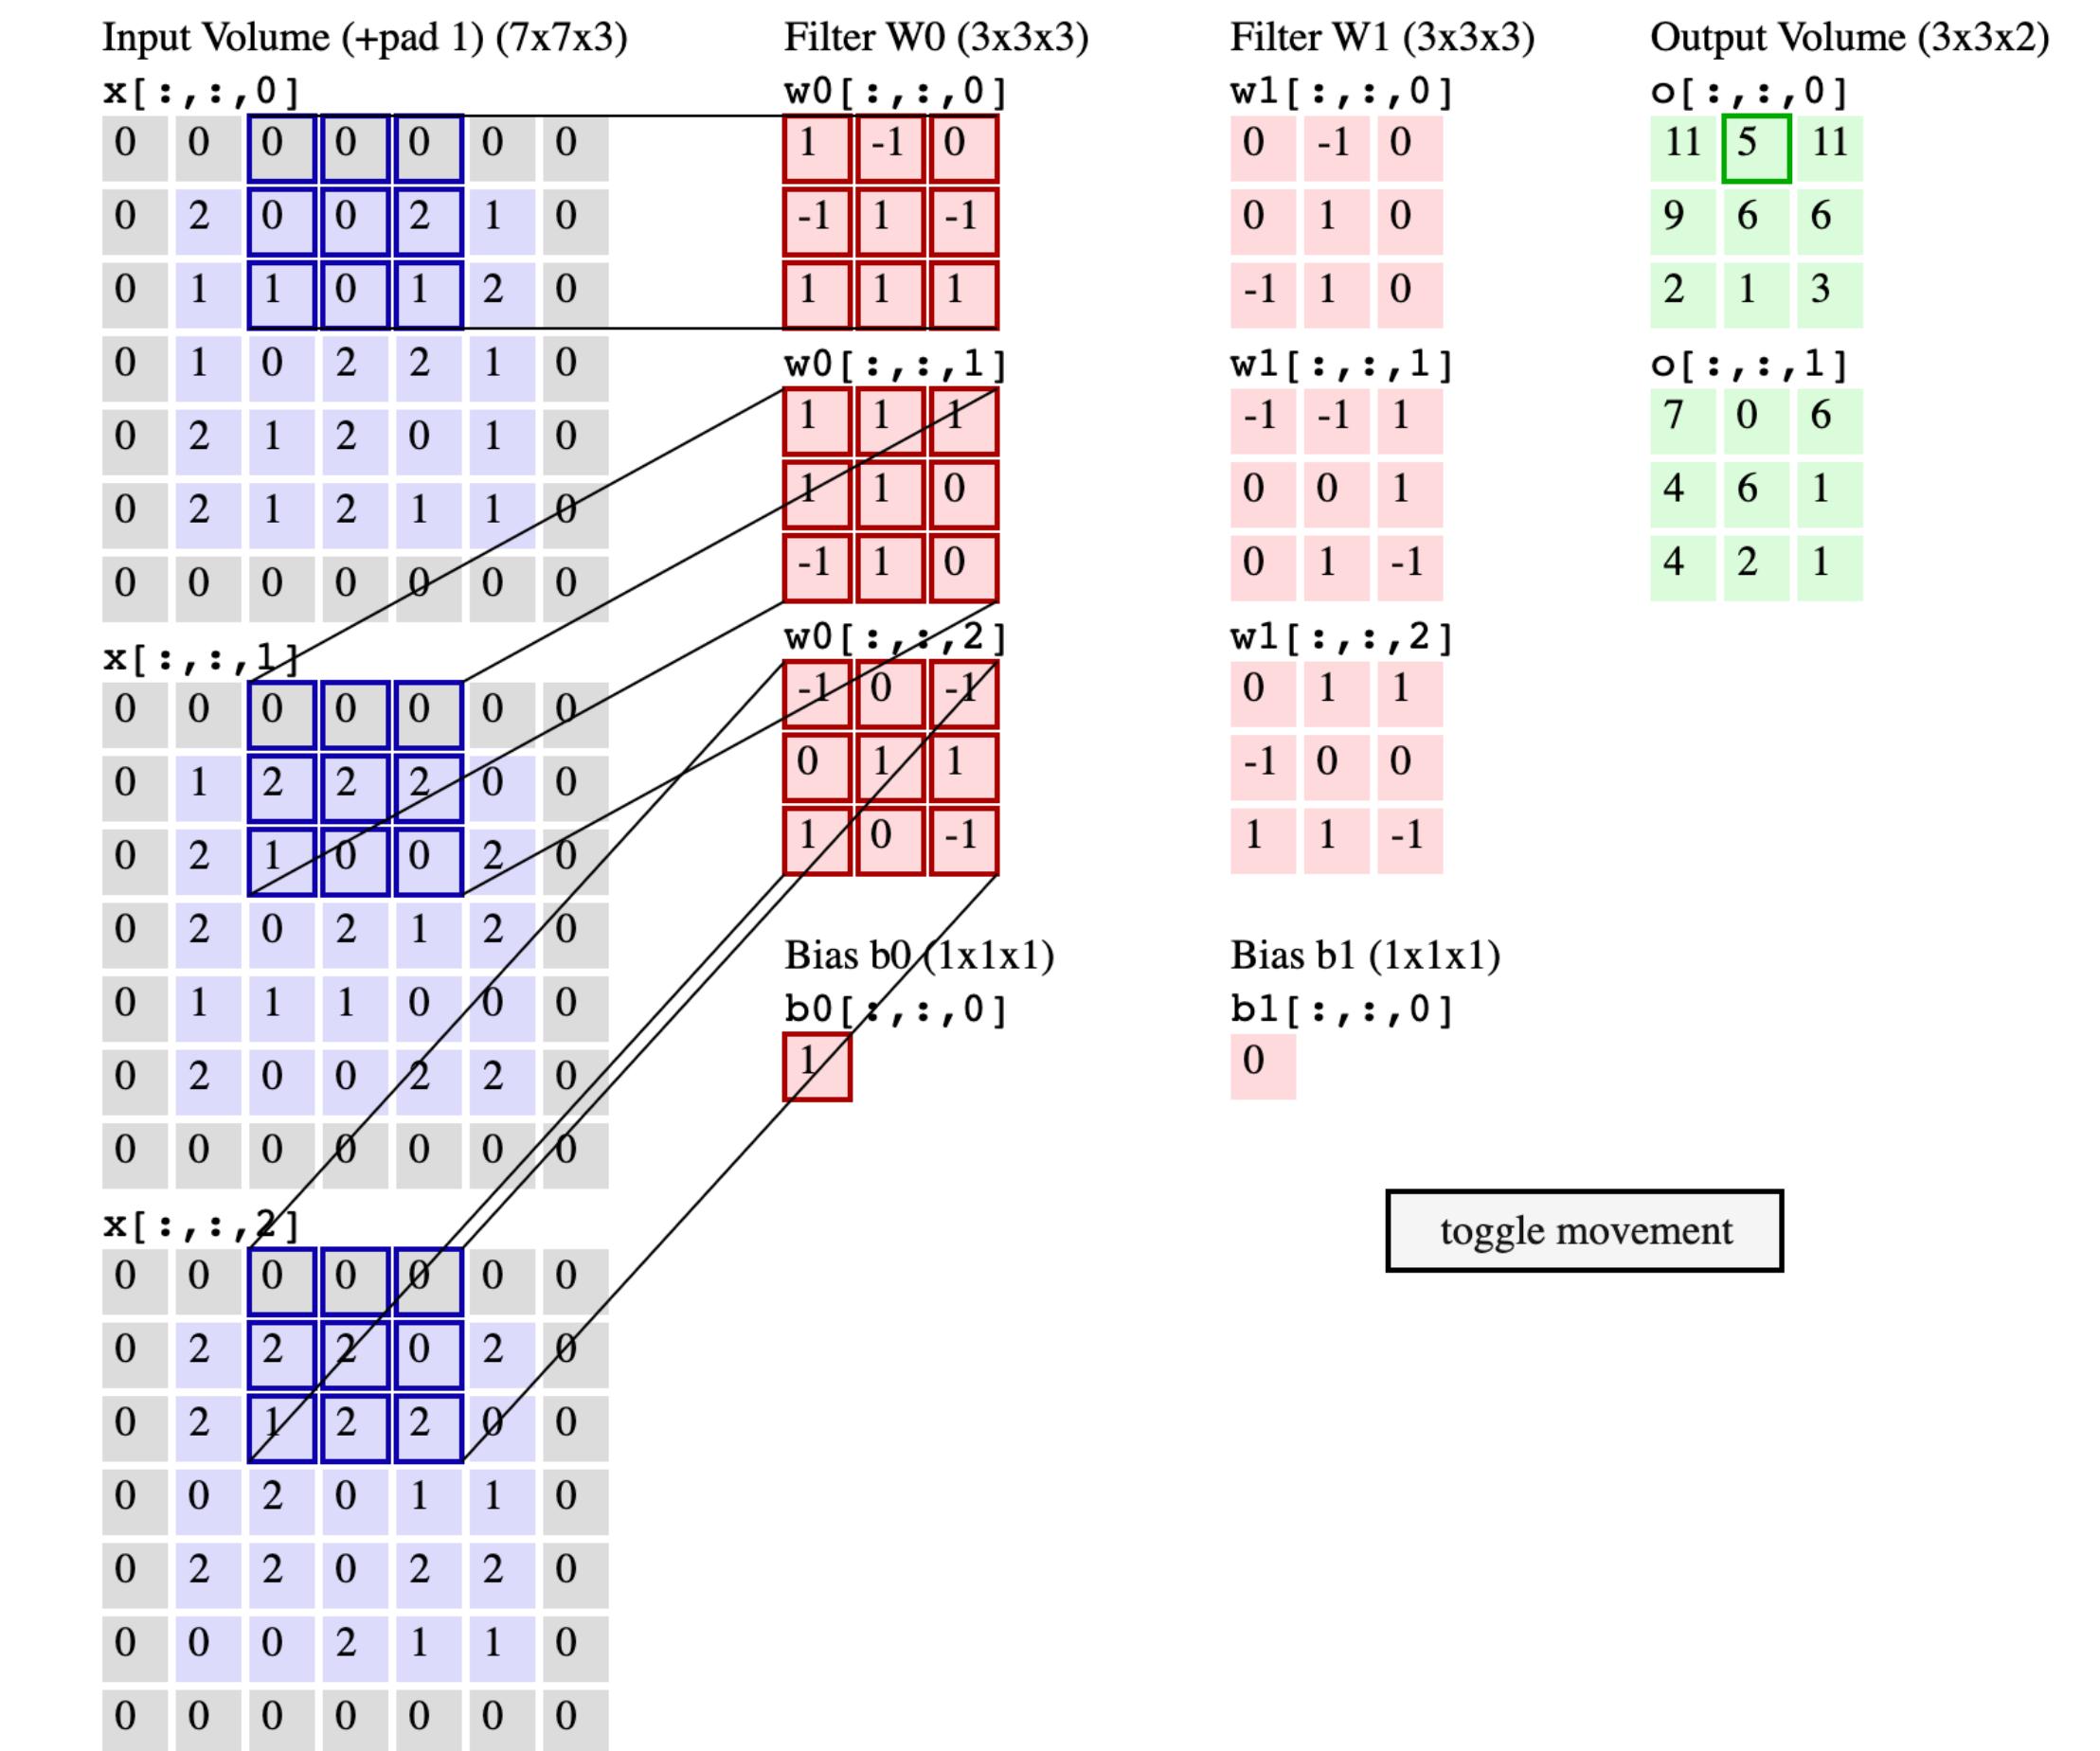

# Bonus: size correspondence after a Conv Layer

- Input size  $(W_1, H_1) = (5,5)$
- Filter size  $F = 3$
- Stride  $S = 2$
- Padding size  $P = 1$
- Output size  $(W_2, H_2) = ?$

$$W_2 = (W_1 - F + 2P)/S + 1 = (5 - 3 + 2)/2 + 1 = 3$$

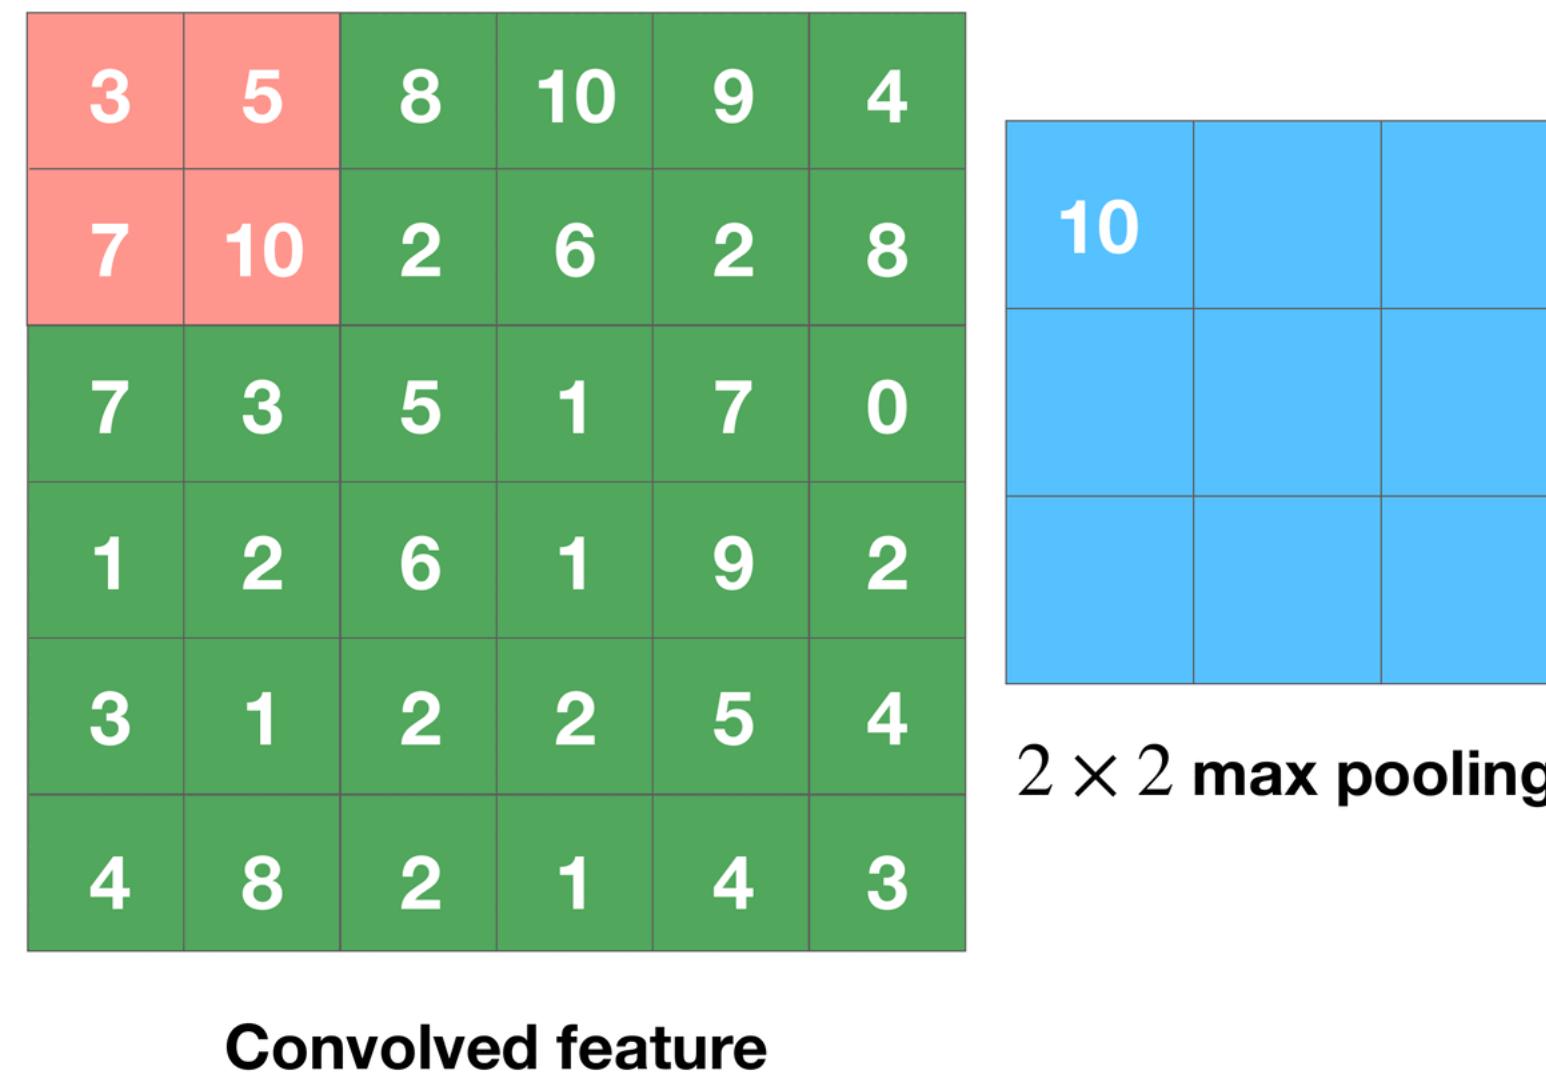

$$H_2 = (H_1 - F + 2P)/S + 1 = (5 - 3 + 2)/2 + 1 = 3$$

# Pooling: often applied after the convolutional layer

Max pooling: returns the maximum value of the portion of the convolved feature that is covered by the kernel

Average pooling: returns the average value of the portion of the convolved feature that is covered by the kernel

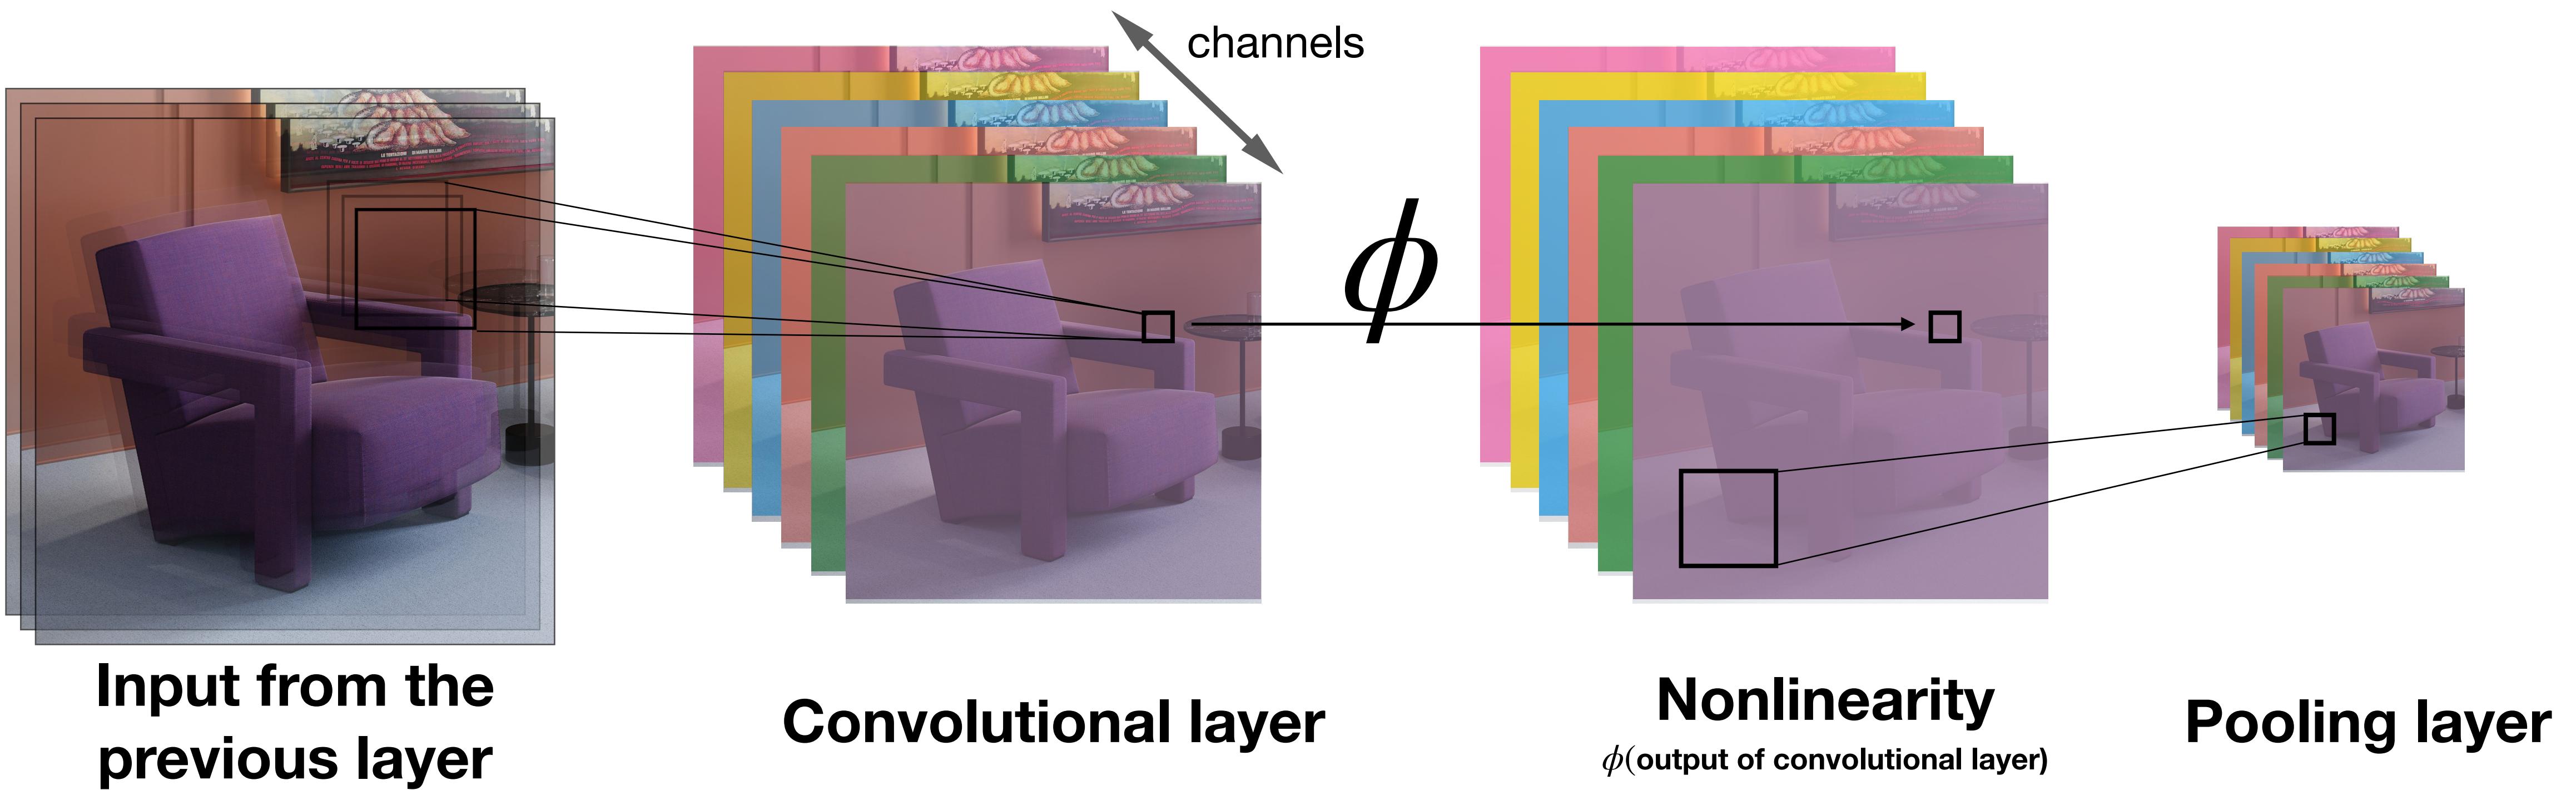

Pooling is a downsampling operation that reduces the spatial dimensions of the convolved feature

Remark: Pooling layers do not have learnable parameters

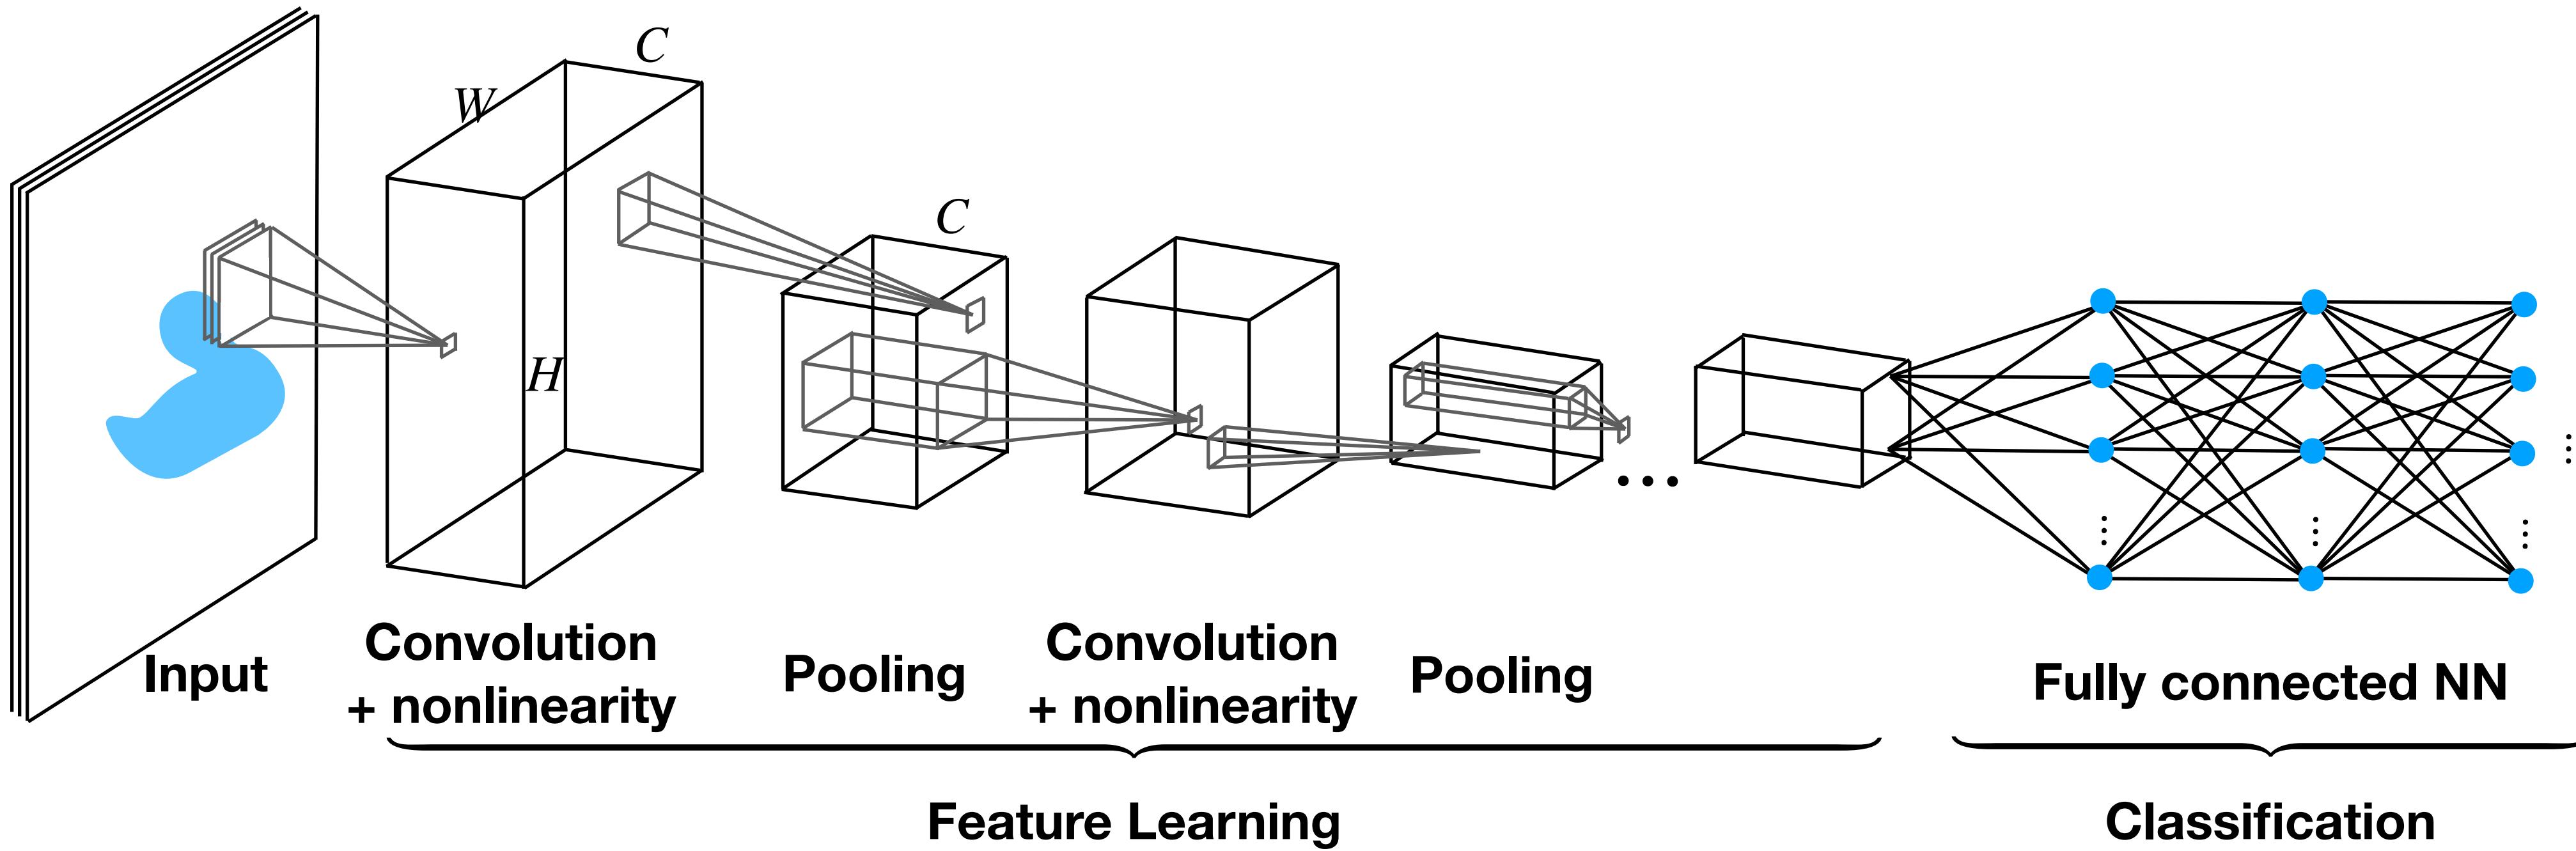

Hyperparameters are the size, type, and stride of the pooling operation

# Non-linearity and convolutional NNs

**Important:** A non-linearity such as ReLU is included after each convolutional layer to make the model non-linear

# Convolutional NNs: General Structure

**Receptive field** (area of input that affects a given neuron) increases with depth:

- First layers extract low-level features, e.g., edges, colors
  - Subsequent layers extract high-level features, e.g., objects
- ConvNet reduces the images to a form easier to process without losing essential features

# Backpropagation with weight sharing

Weight sharing is used in CNN: many edges use the same weights

Training:

1. Run backpropagation as if the weights were not shared (treat each weight as an independent variable)
2. Once the gradient is computed, sum the gradients of all edges that share the same weight

Why: let  $f(x, y, z) : \mathbb{R}^3 \rightarrow \mathbb{R}$  and  $g(x, y) = f(x, y, x)$

$$\left( \frac{\partial g}{\partial x}(x, y), \frac{\partial g}{\partial y}(x, y) \right) = \left( \frac{\partial f}{\partial x}(x, y, x) + \frac{\partial f}{\partial z}(x, y, x), \frac{\partial f}{\partial y}(x, y, x) \right)$$

# Learned Convolutional Filters on ImageNet

Source: [ImageNet Classification with Deep Convolutional Neural Networks \(NeurIPS 2012\)](#)

- Filters of the **first** layer can be interpretable
- Edge and color detectors typically emerge when trained on large datasets

# Individual Activations Can Be Interpretable

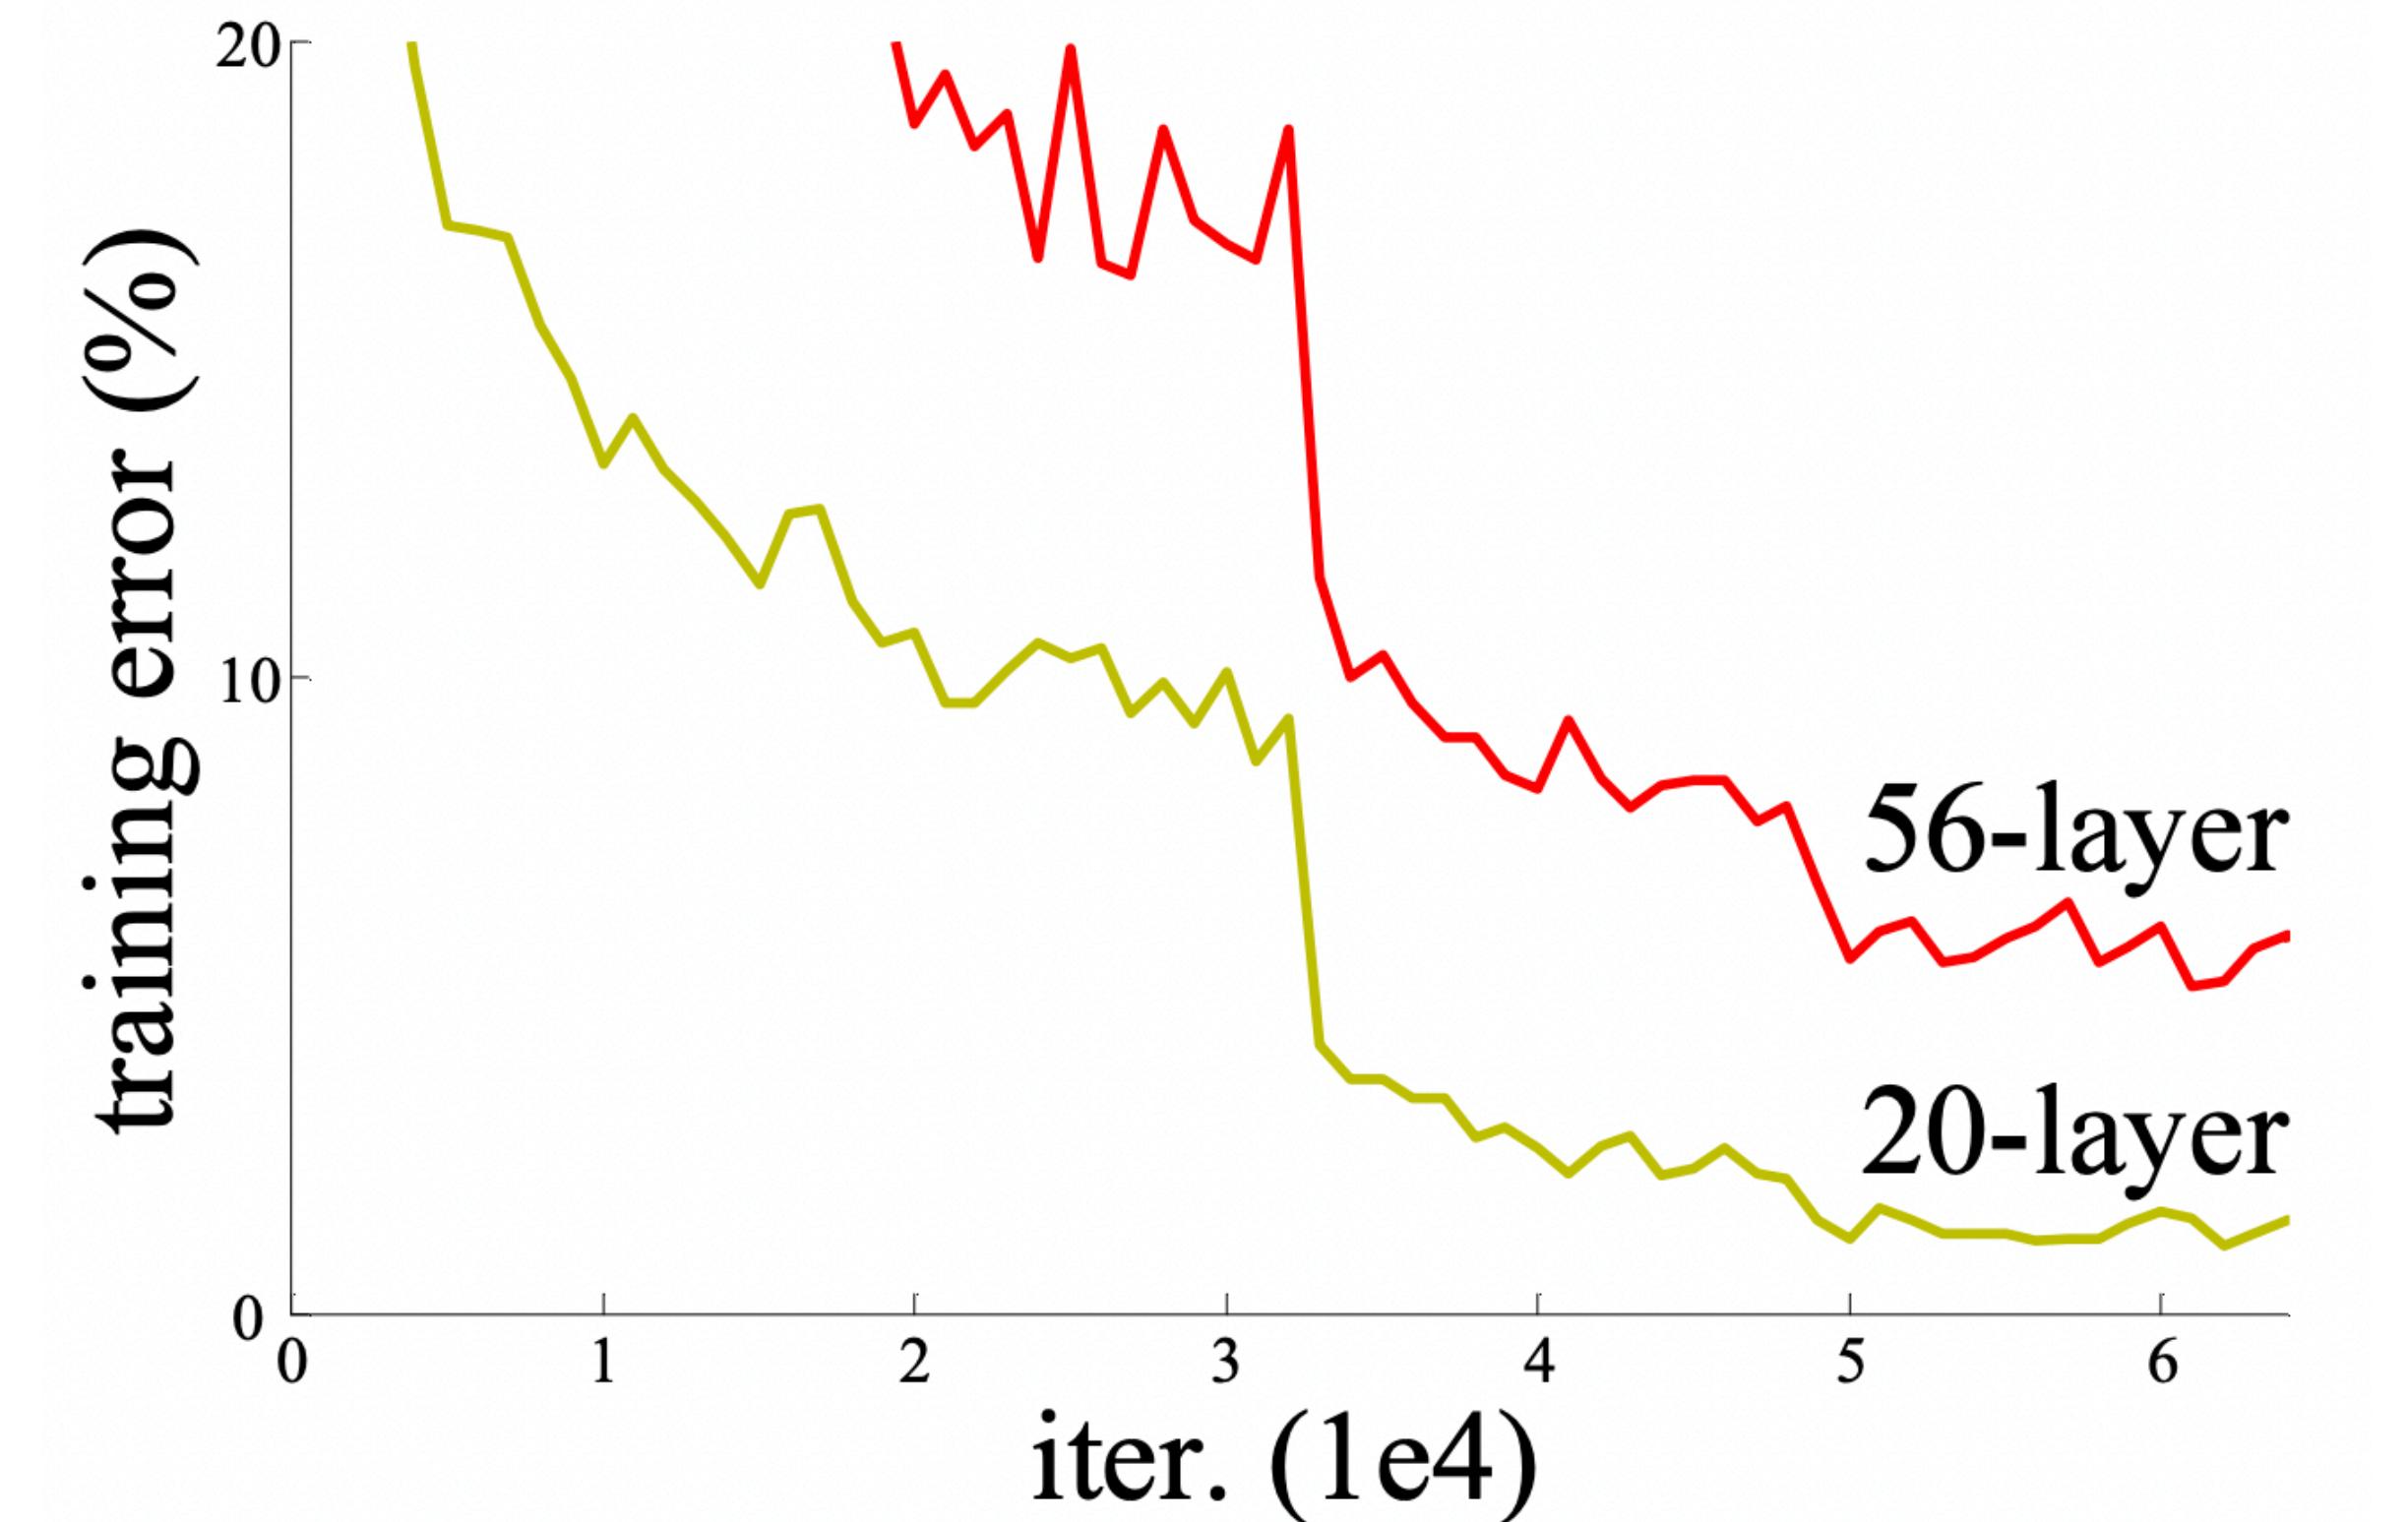

Source: [Rich feature hierarchies for accurate object detection and semantic segmentation](#) (CVPR 2014)

- Receptive fields and activation values are drawn in white
- Each activation detects some **pattern** or **object** (not always interpretable)
- Activations in later layers detect more complex patterns

# Residual Networks

# Skip Connections and Residuals

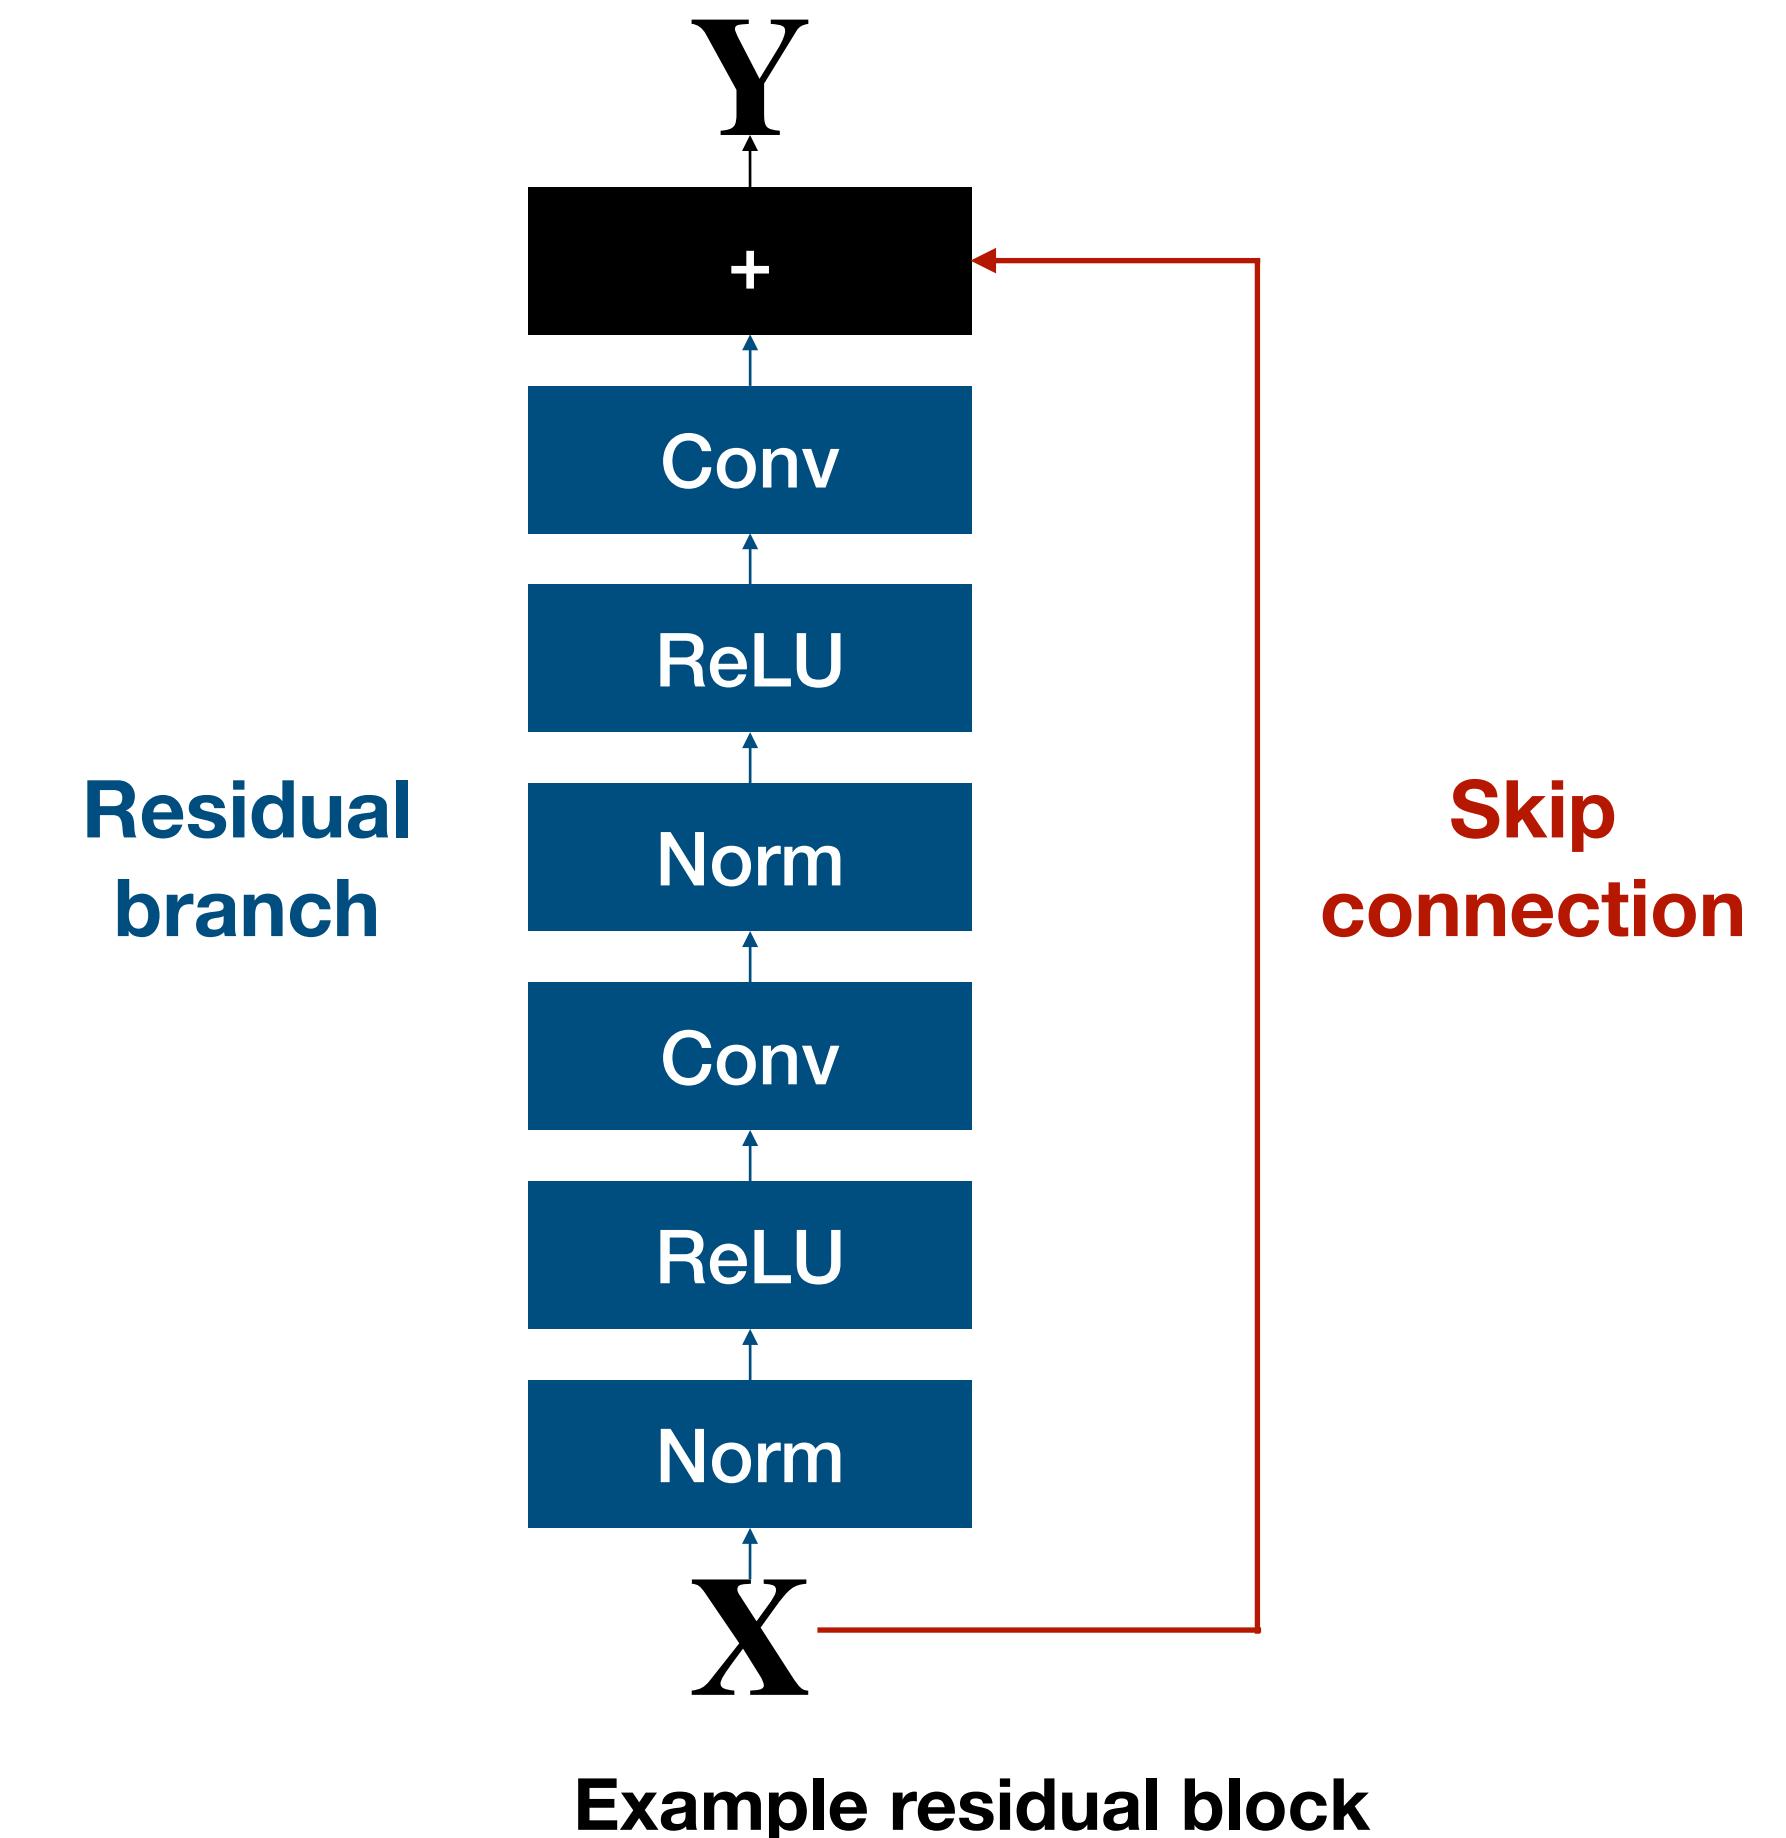

- **Starting point:** Adding more layers should lead to the same or lower training loss as they can learn the identity function
- **ResNet paper** indicates that this is not always the case
- **Solution:** add a *skip connection* around some layers  $F(\mathbf{X})$
- **Standard network:**  $\mathbf{Y} = F(\mathbf{X})$
- **Residual network:**  $\mathbf{Y} = R(\mathbf{X}) + \mathbf{X}$  where  $R(\mathbf{X})$  is called a residual branch

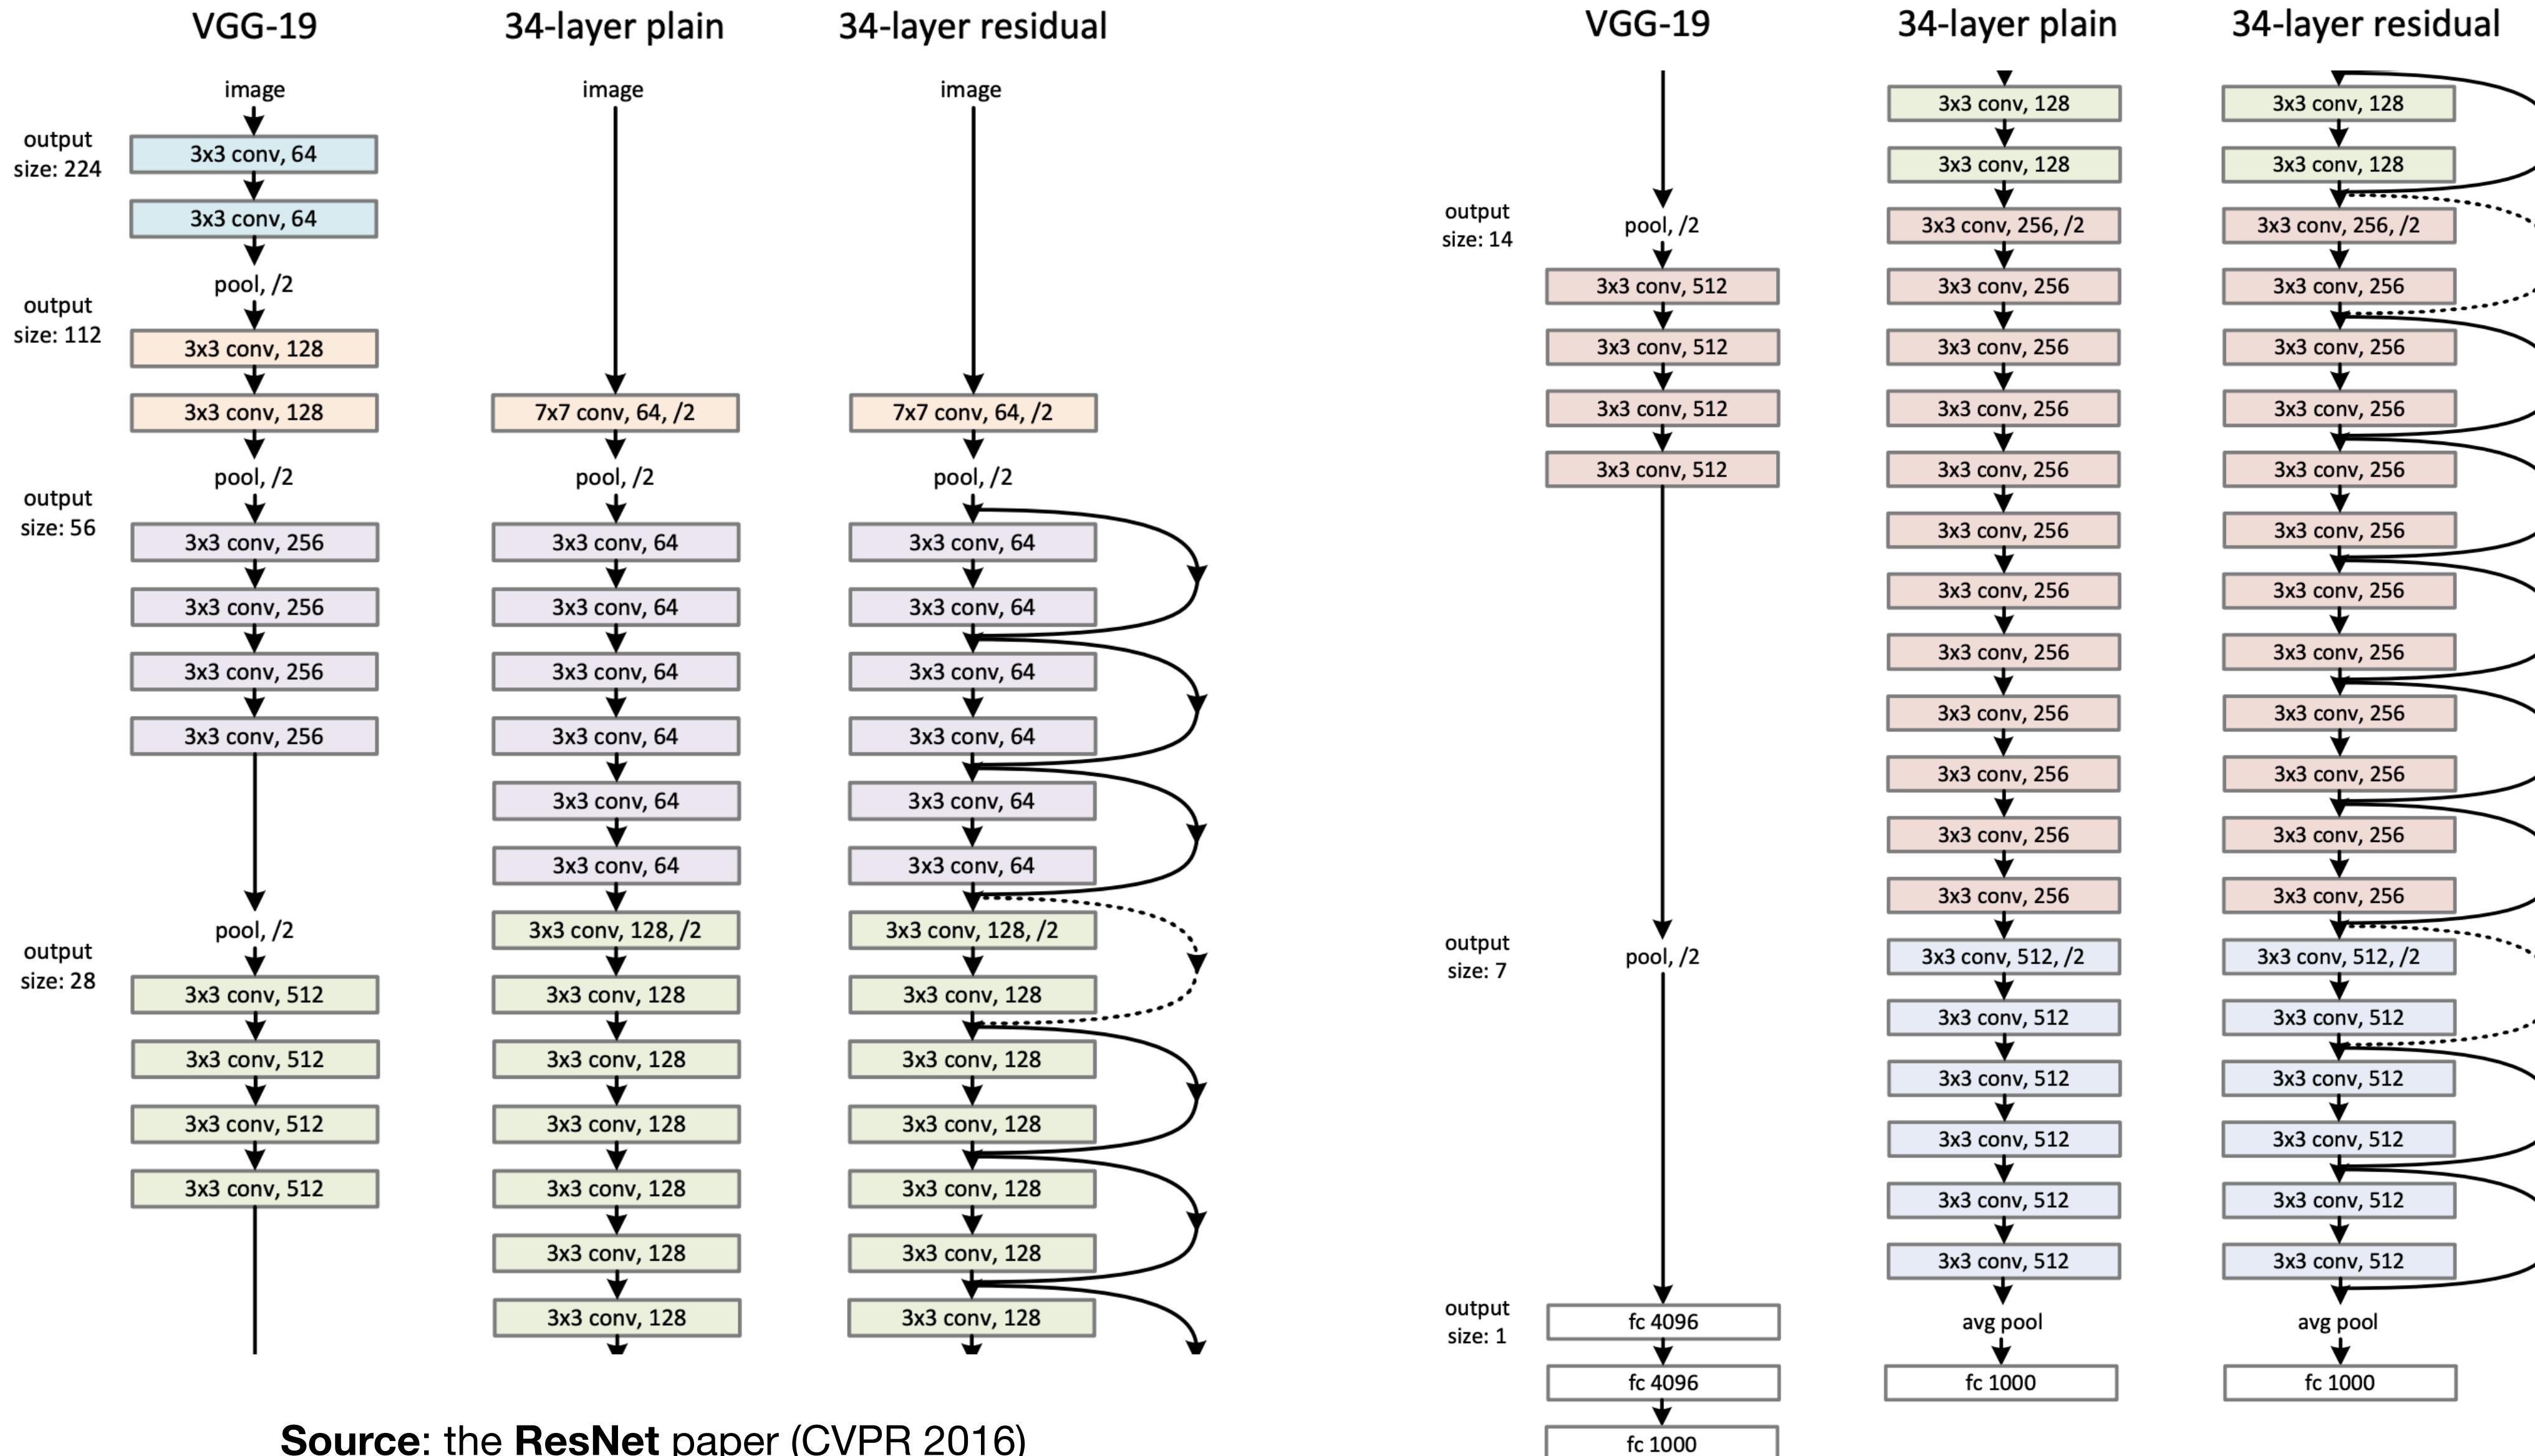

Observation from the **ResNet paper**: deeper CNNs are harder to train

# Skip Connections and Residuals

- **Example of  $R(\mathbf{X})$ :** see on the right
- **Technical detail:** If  $\text{size}(\mathbf{Y}) \neq \text{size}(\mathbf{X})$ , additional operations are needed on the skip connection to match the dimensions
- Skip connections address the observed convergence issue, making the training of very deep networks (with hundreds of layers) feasible
- Skip connections are used in almost all modern neural networks (including CNNs and transformers)

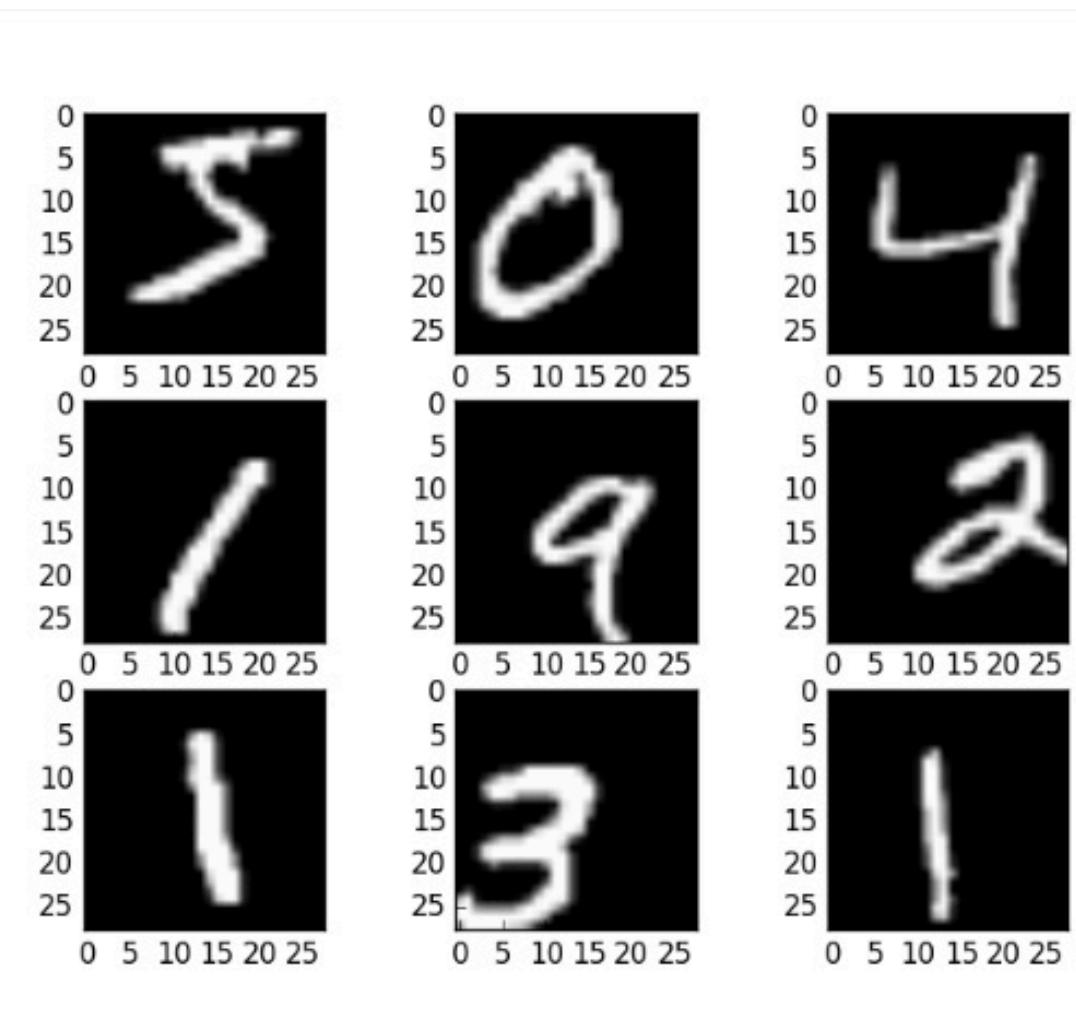

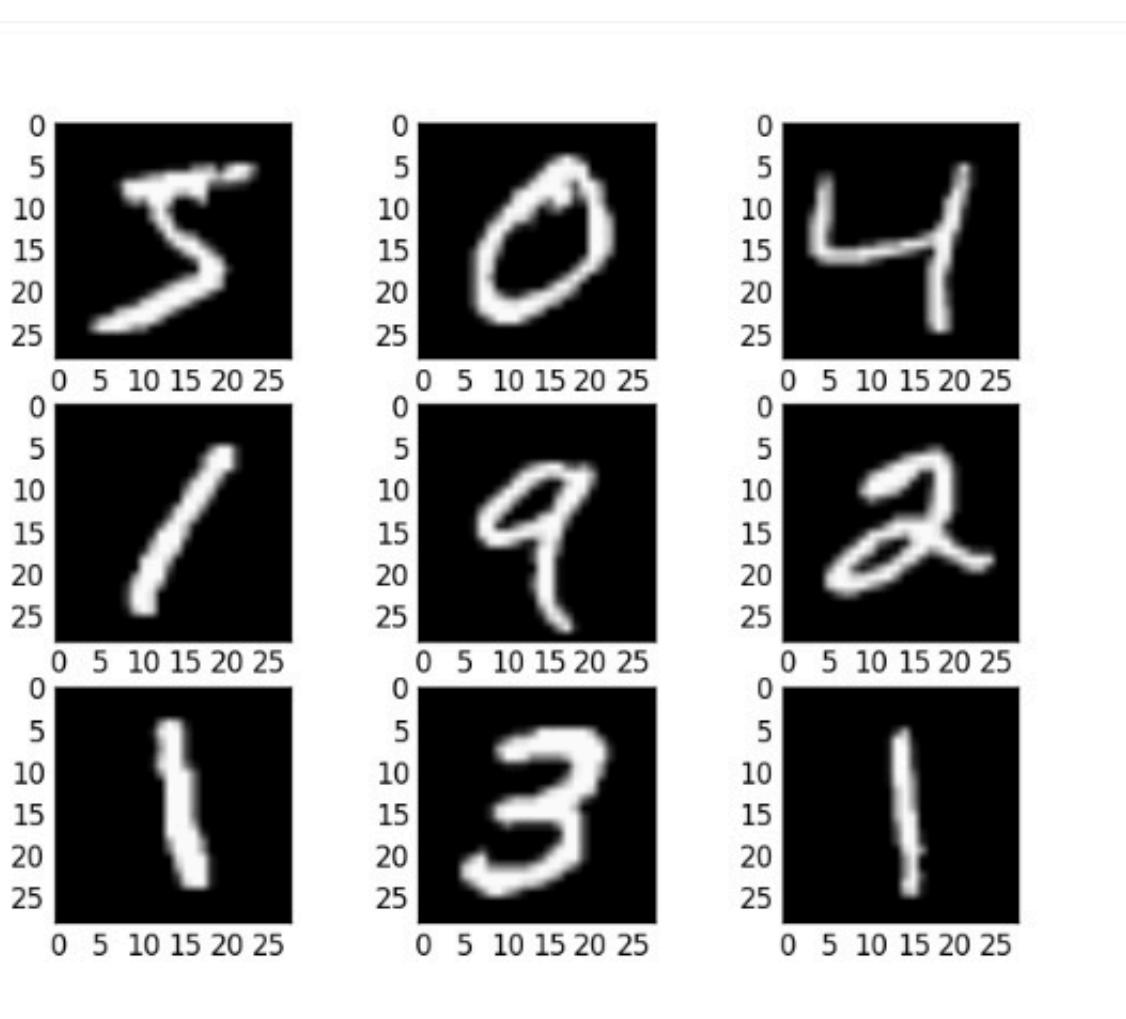

# Popular architectures: VGG vs. ResNet

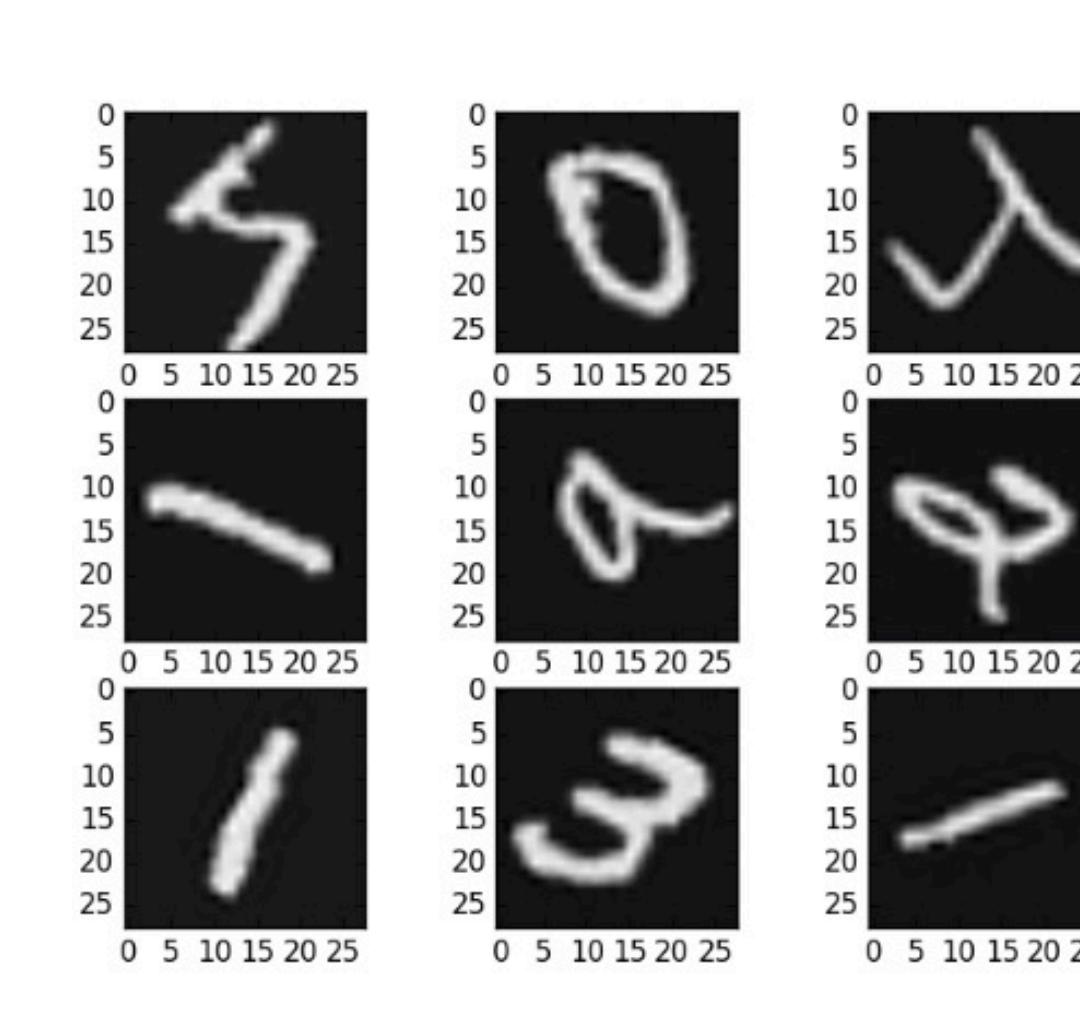

# Data Augmentation

# Data augmentation: generate new data from the data

Shifted MNIST

Rotated MNIST

Note dangers  
of excessive  
augmentation!

May eventually  
confuse 6 and 9

Transformation  $\tau : \mathbb{R}^d \rightarrow \mathbb{R}^d$  which preserves the labels (i.e.,  $y_x = y_{\tau(x)}$ )

$$S = S_{train} \cup \{(\tau(x_i), y_i)\}_{i=1}^n$$

- We train on more data
- Encourages models to be invariant to  $\tau$
- It can be seen as regularization
- These transformations are task and dataset specific

# Data augmentation: pictures can also be cropped, resized, or perturbed by a small amount of noise

(a) Original

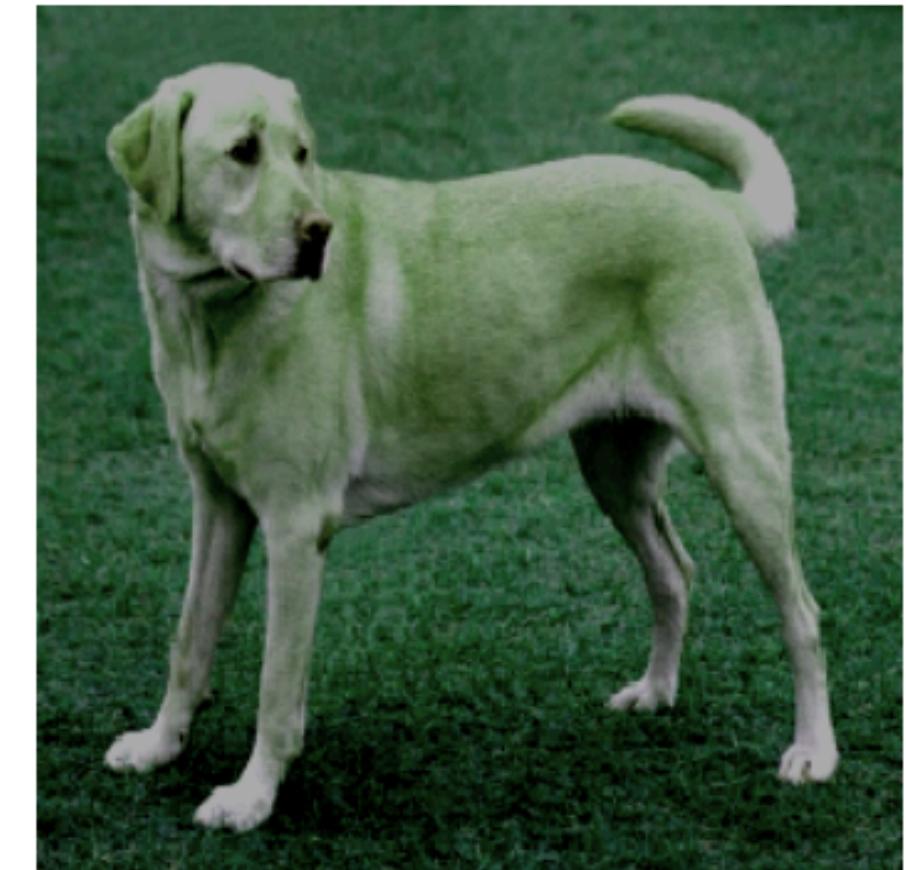

(b) Crop and resize

(c) Crop, resize (and flip)

(d) Color distort. (drop)

(e) Color distort. (jitter)

(f) Rotate  $\{90^\circ, 180^\circ, 270^\circ\}$

(g) Cutout

(h) Gaussian noise

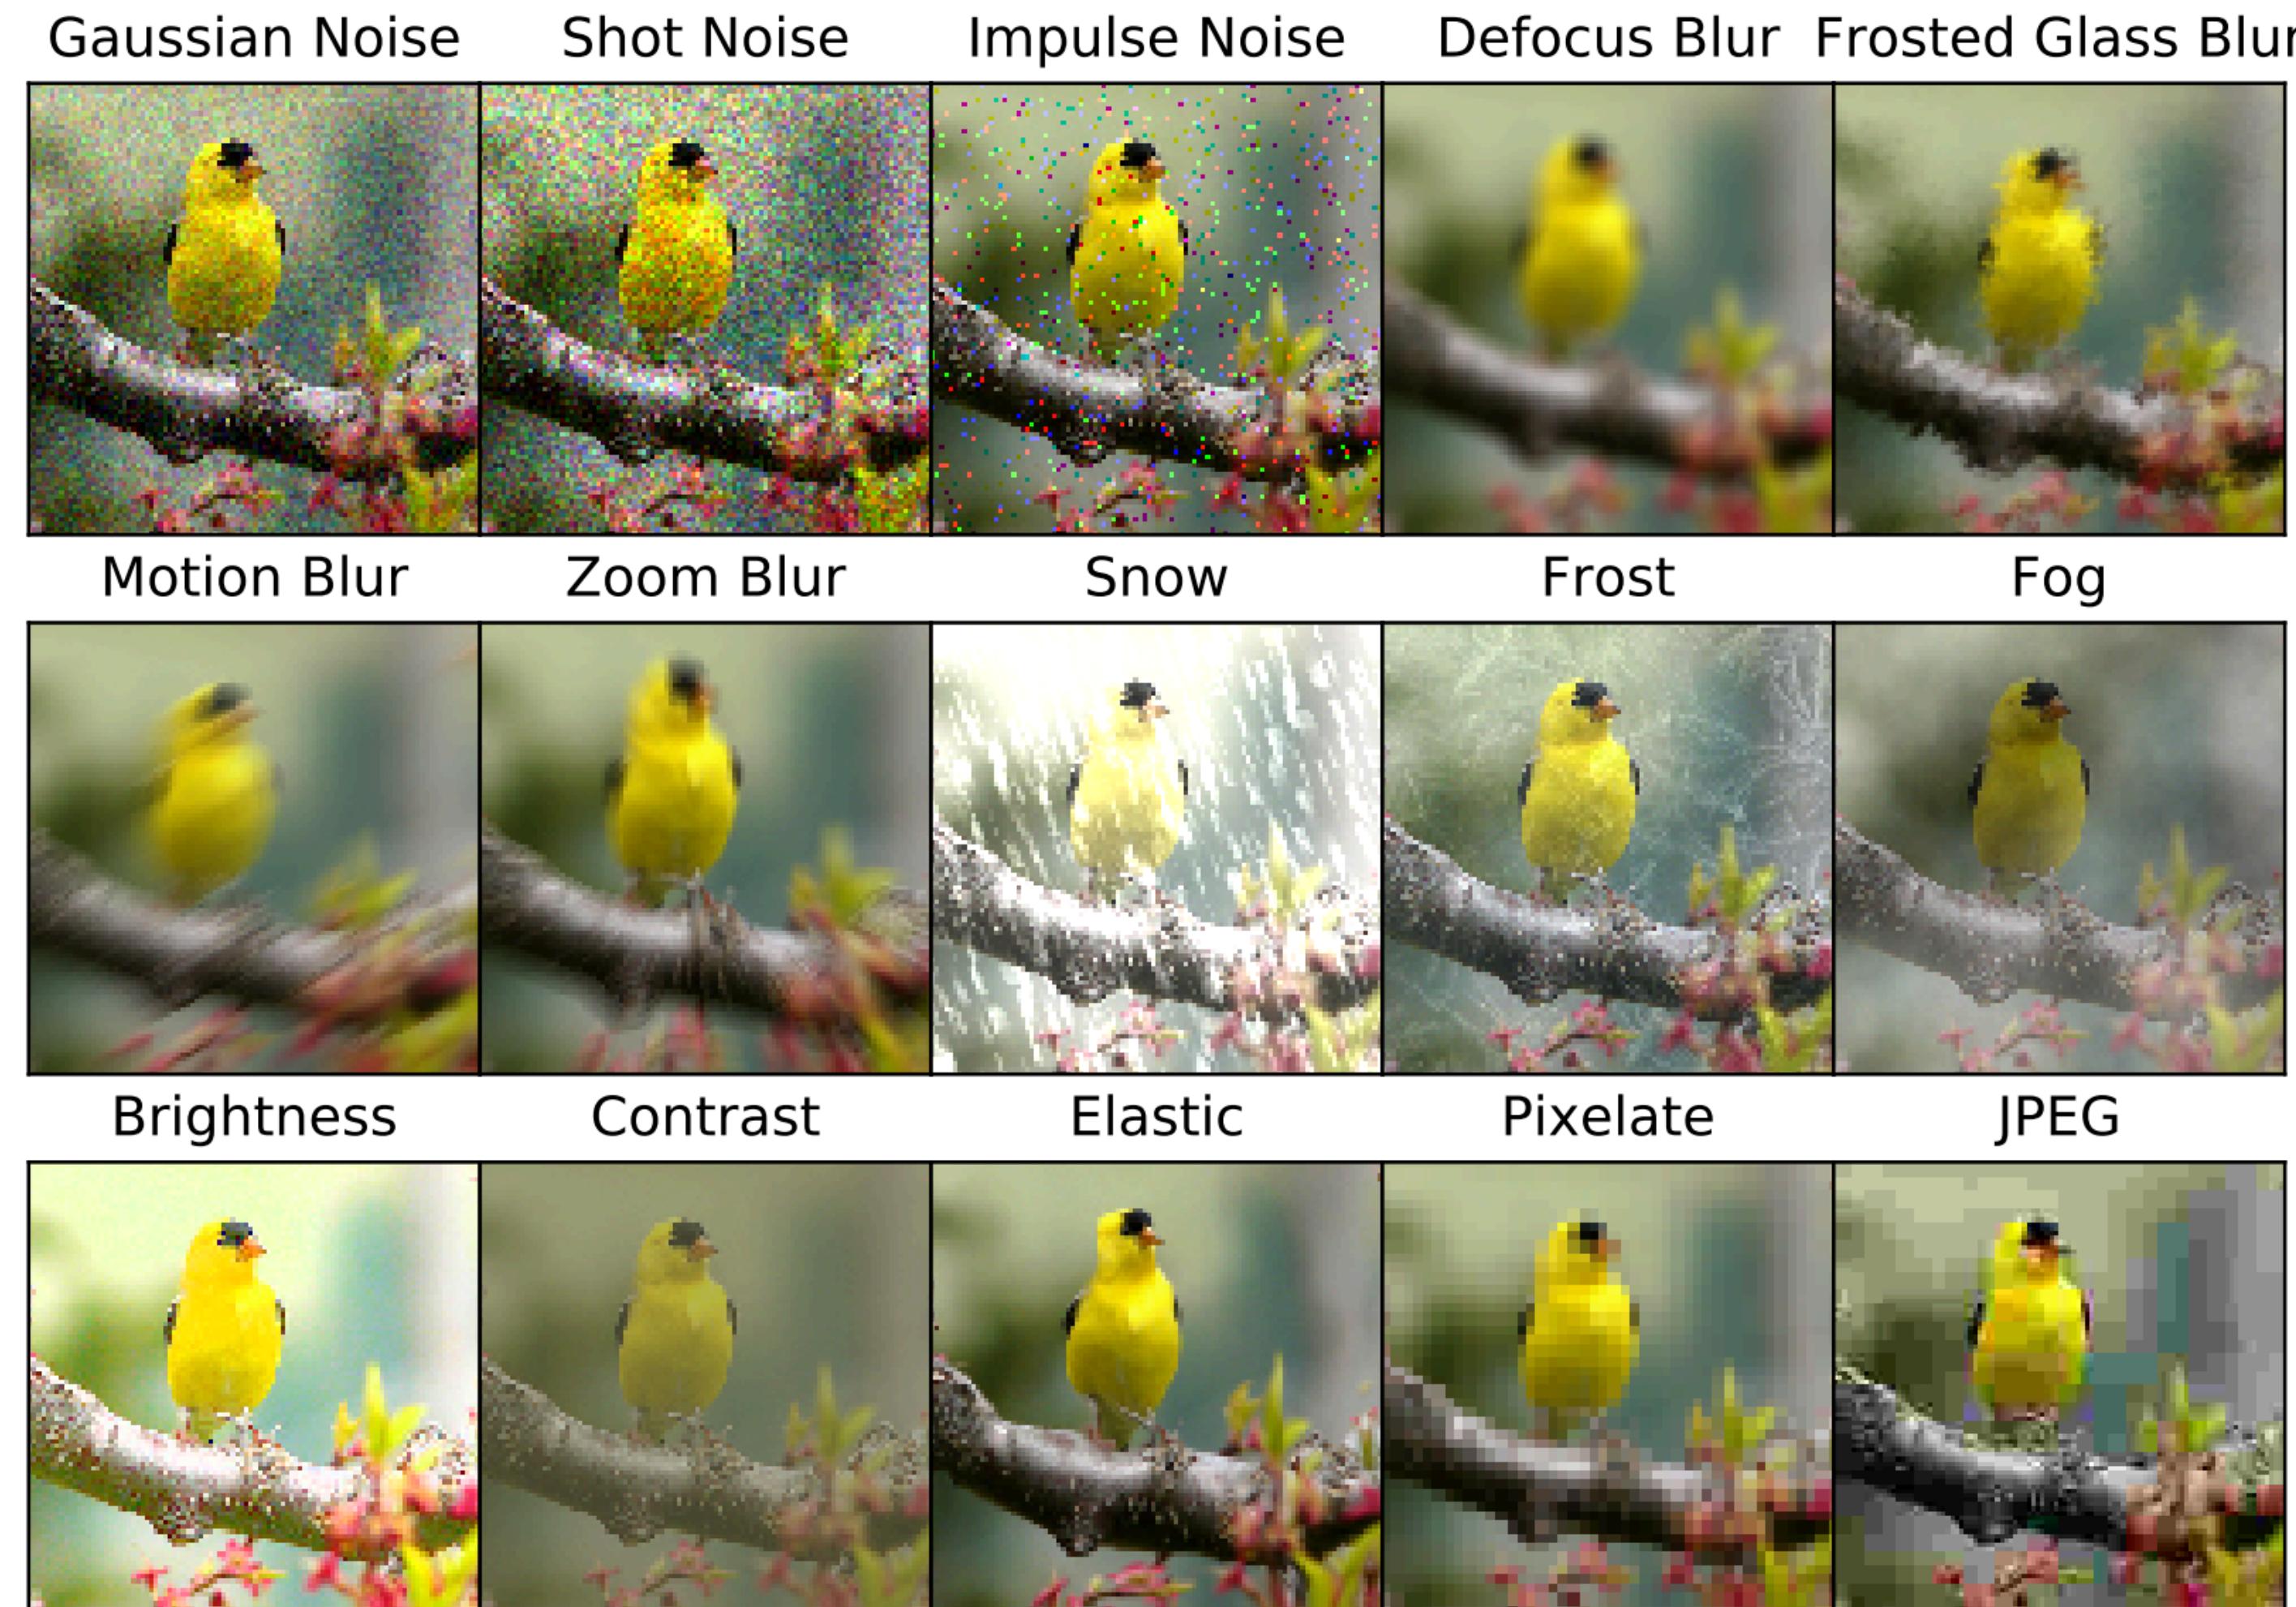

(i) Gaussian blur

(j) Sobel filtering

# Data augmentation: generated corruptions

# Weight Decay

# Weight decay: $\ell_2$ -regularization for NNs

It is standard practice to regularize weights without regularizing bias terms:

$$\min \mathcal{L} + \frac{\lambda}{2} \sum_l \|\mathbf{W}^{(l)}\|_F^2$$

Weight decay [1] favors small weights which can aid in generalization and optimization

Optimization with gradient descent:

$$(\mathbf{w}_{i,j}^{(l)})_{t+1} = (\mathbf{w}_{i,j}^{(l)})_t - \eta \nabla \mathcal{L} - \eta \lambda (\mathbf{w}_{i,j}^{(l)})_t = \underbrace{(1 - \eta \lambda)}_{\text{weight decay}} (\mathbf{w}_{i,j}^{(l)})_t - \eta \nabla \mathcal{L}$$

Interaction with BatchNorm:

- $\text{BN}(\mathbf{WX}) = \text{BN}(\alpha \mathbf{WX})$  for  $\alpha \in \mathbb{R}_{>0}$  (assuming  $\varepsilon \approx 0$ )
- BN is scale invariant in  $\mathbf{W}$ , hence there is **no direct regularization effect from WD**
- However, the training dynamics differ [2]

# **Dropout**

# Dropout: randomly drop nodes

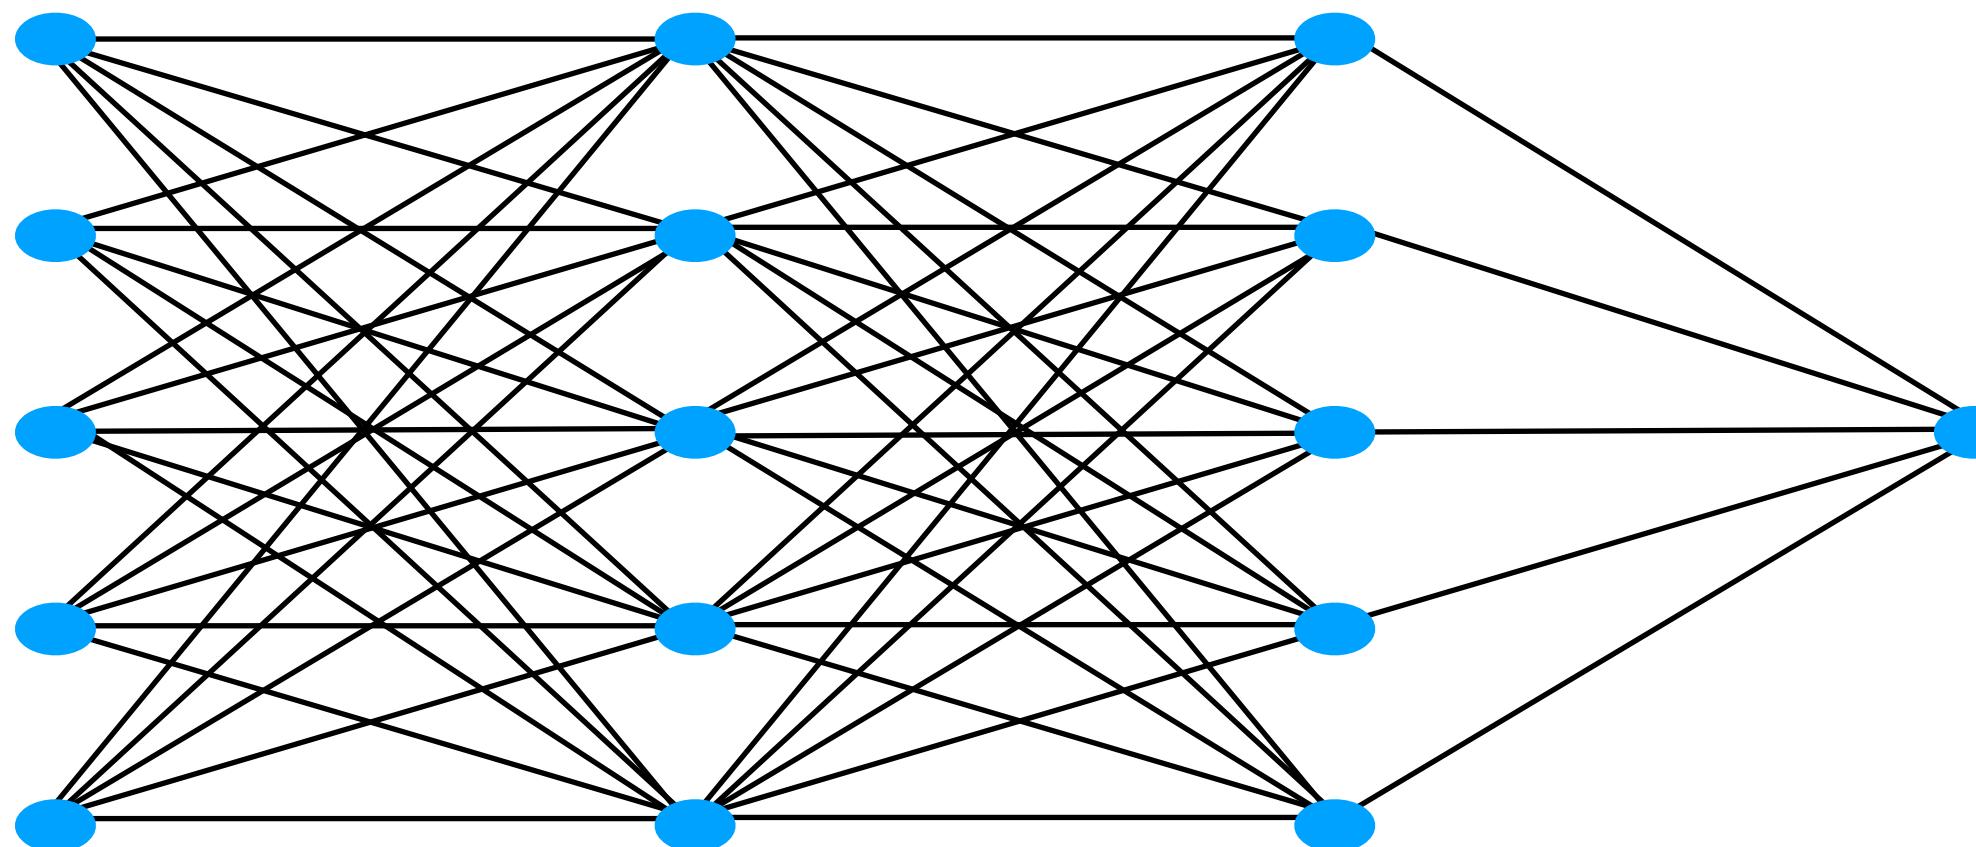

Def: At each training step, retain with probability  $p^{(l)}$  each node in layer  $(l)$ :

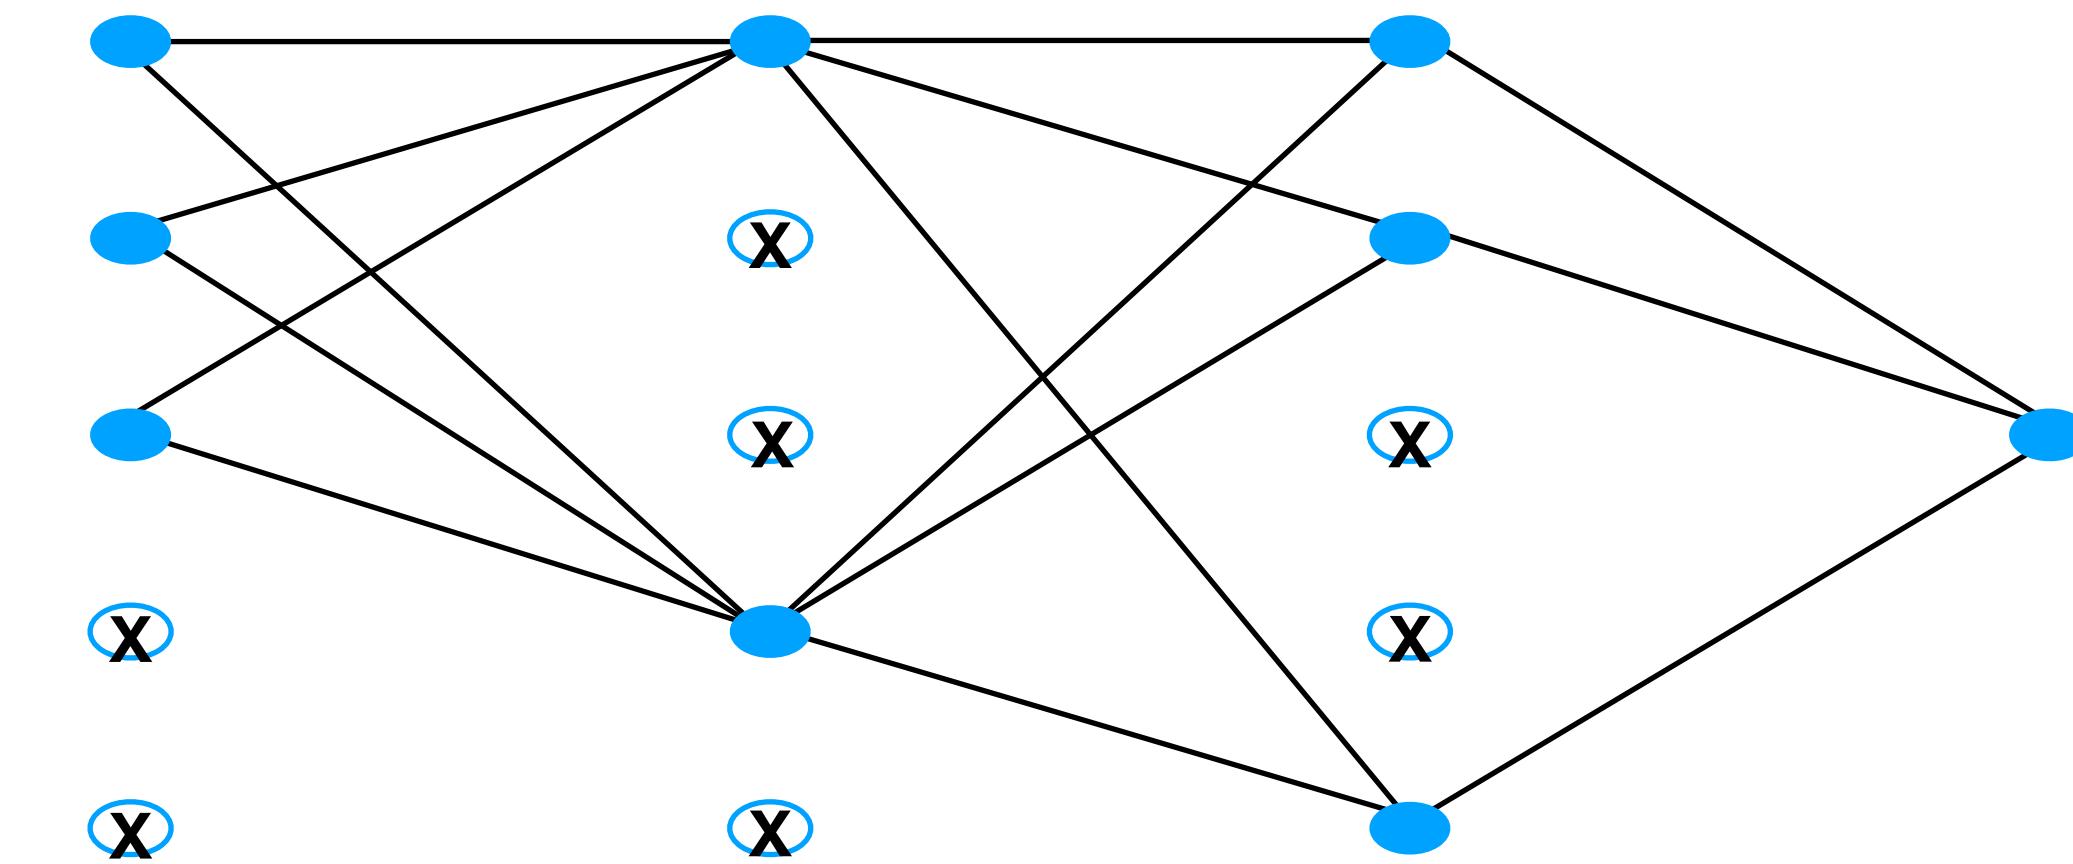

Note: In practice we drop nodes independently for each element of a mini-batch

# Dropout: training phase

Def: At each training step, retain with probability  $p^{(l)}$  each node in layer  $(l)$ :

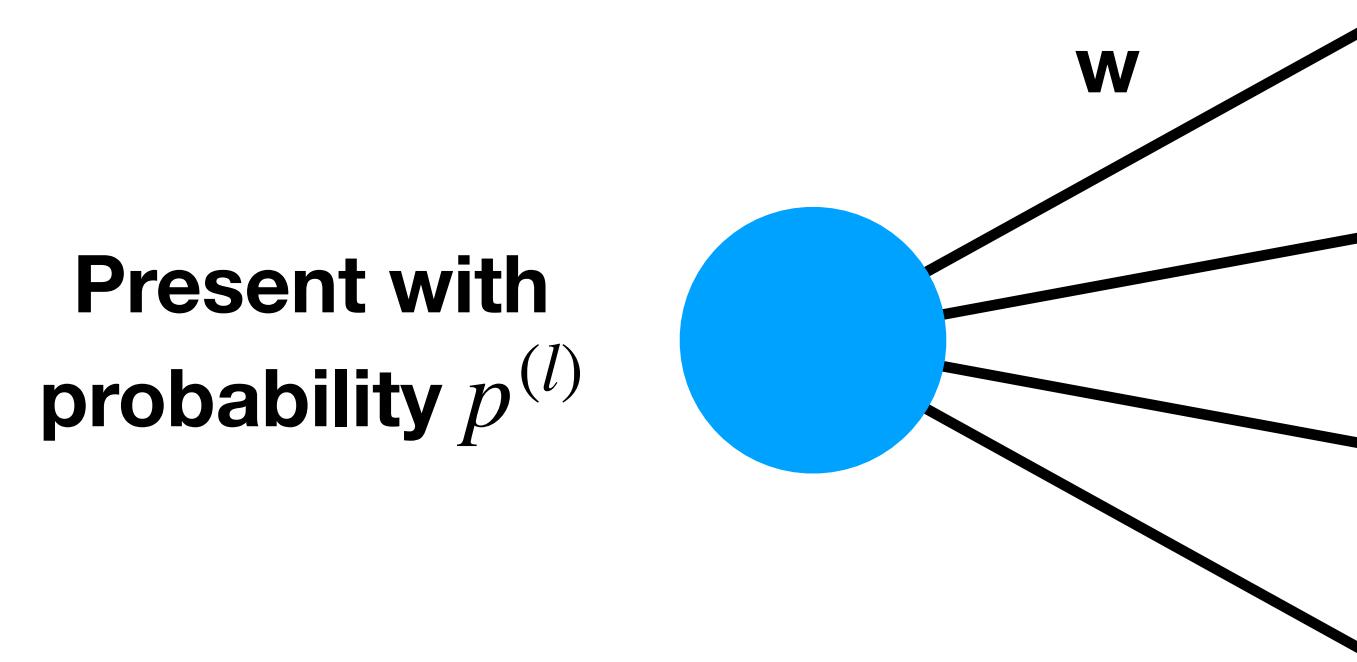

Original network

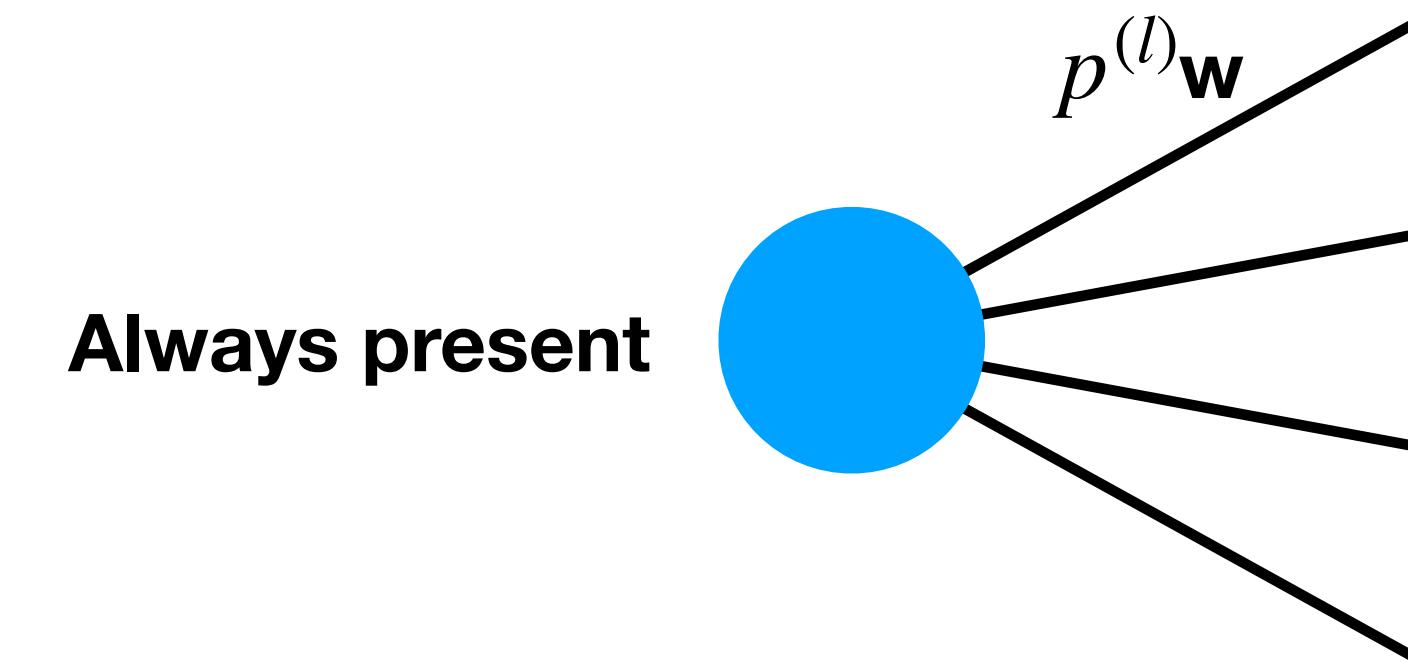

Random subnetwork

Run one step of SGD on the subnetwork and update the weights

# Dropout: testing phase

At training time

At test time

**Note:** Variance is generally not preserved and as a result Dropout often works poorly with normalization

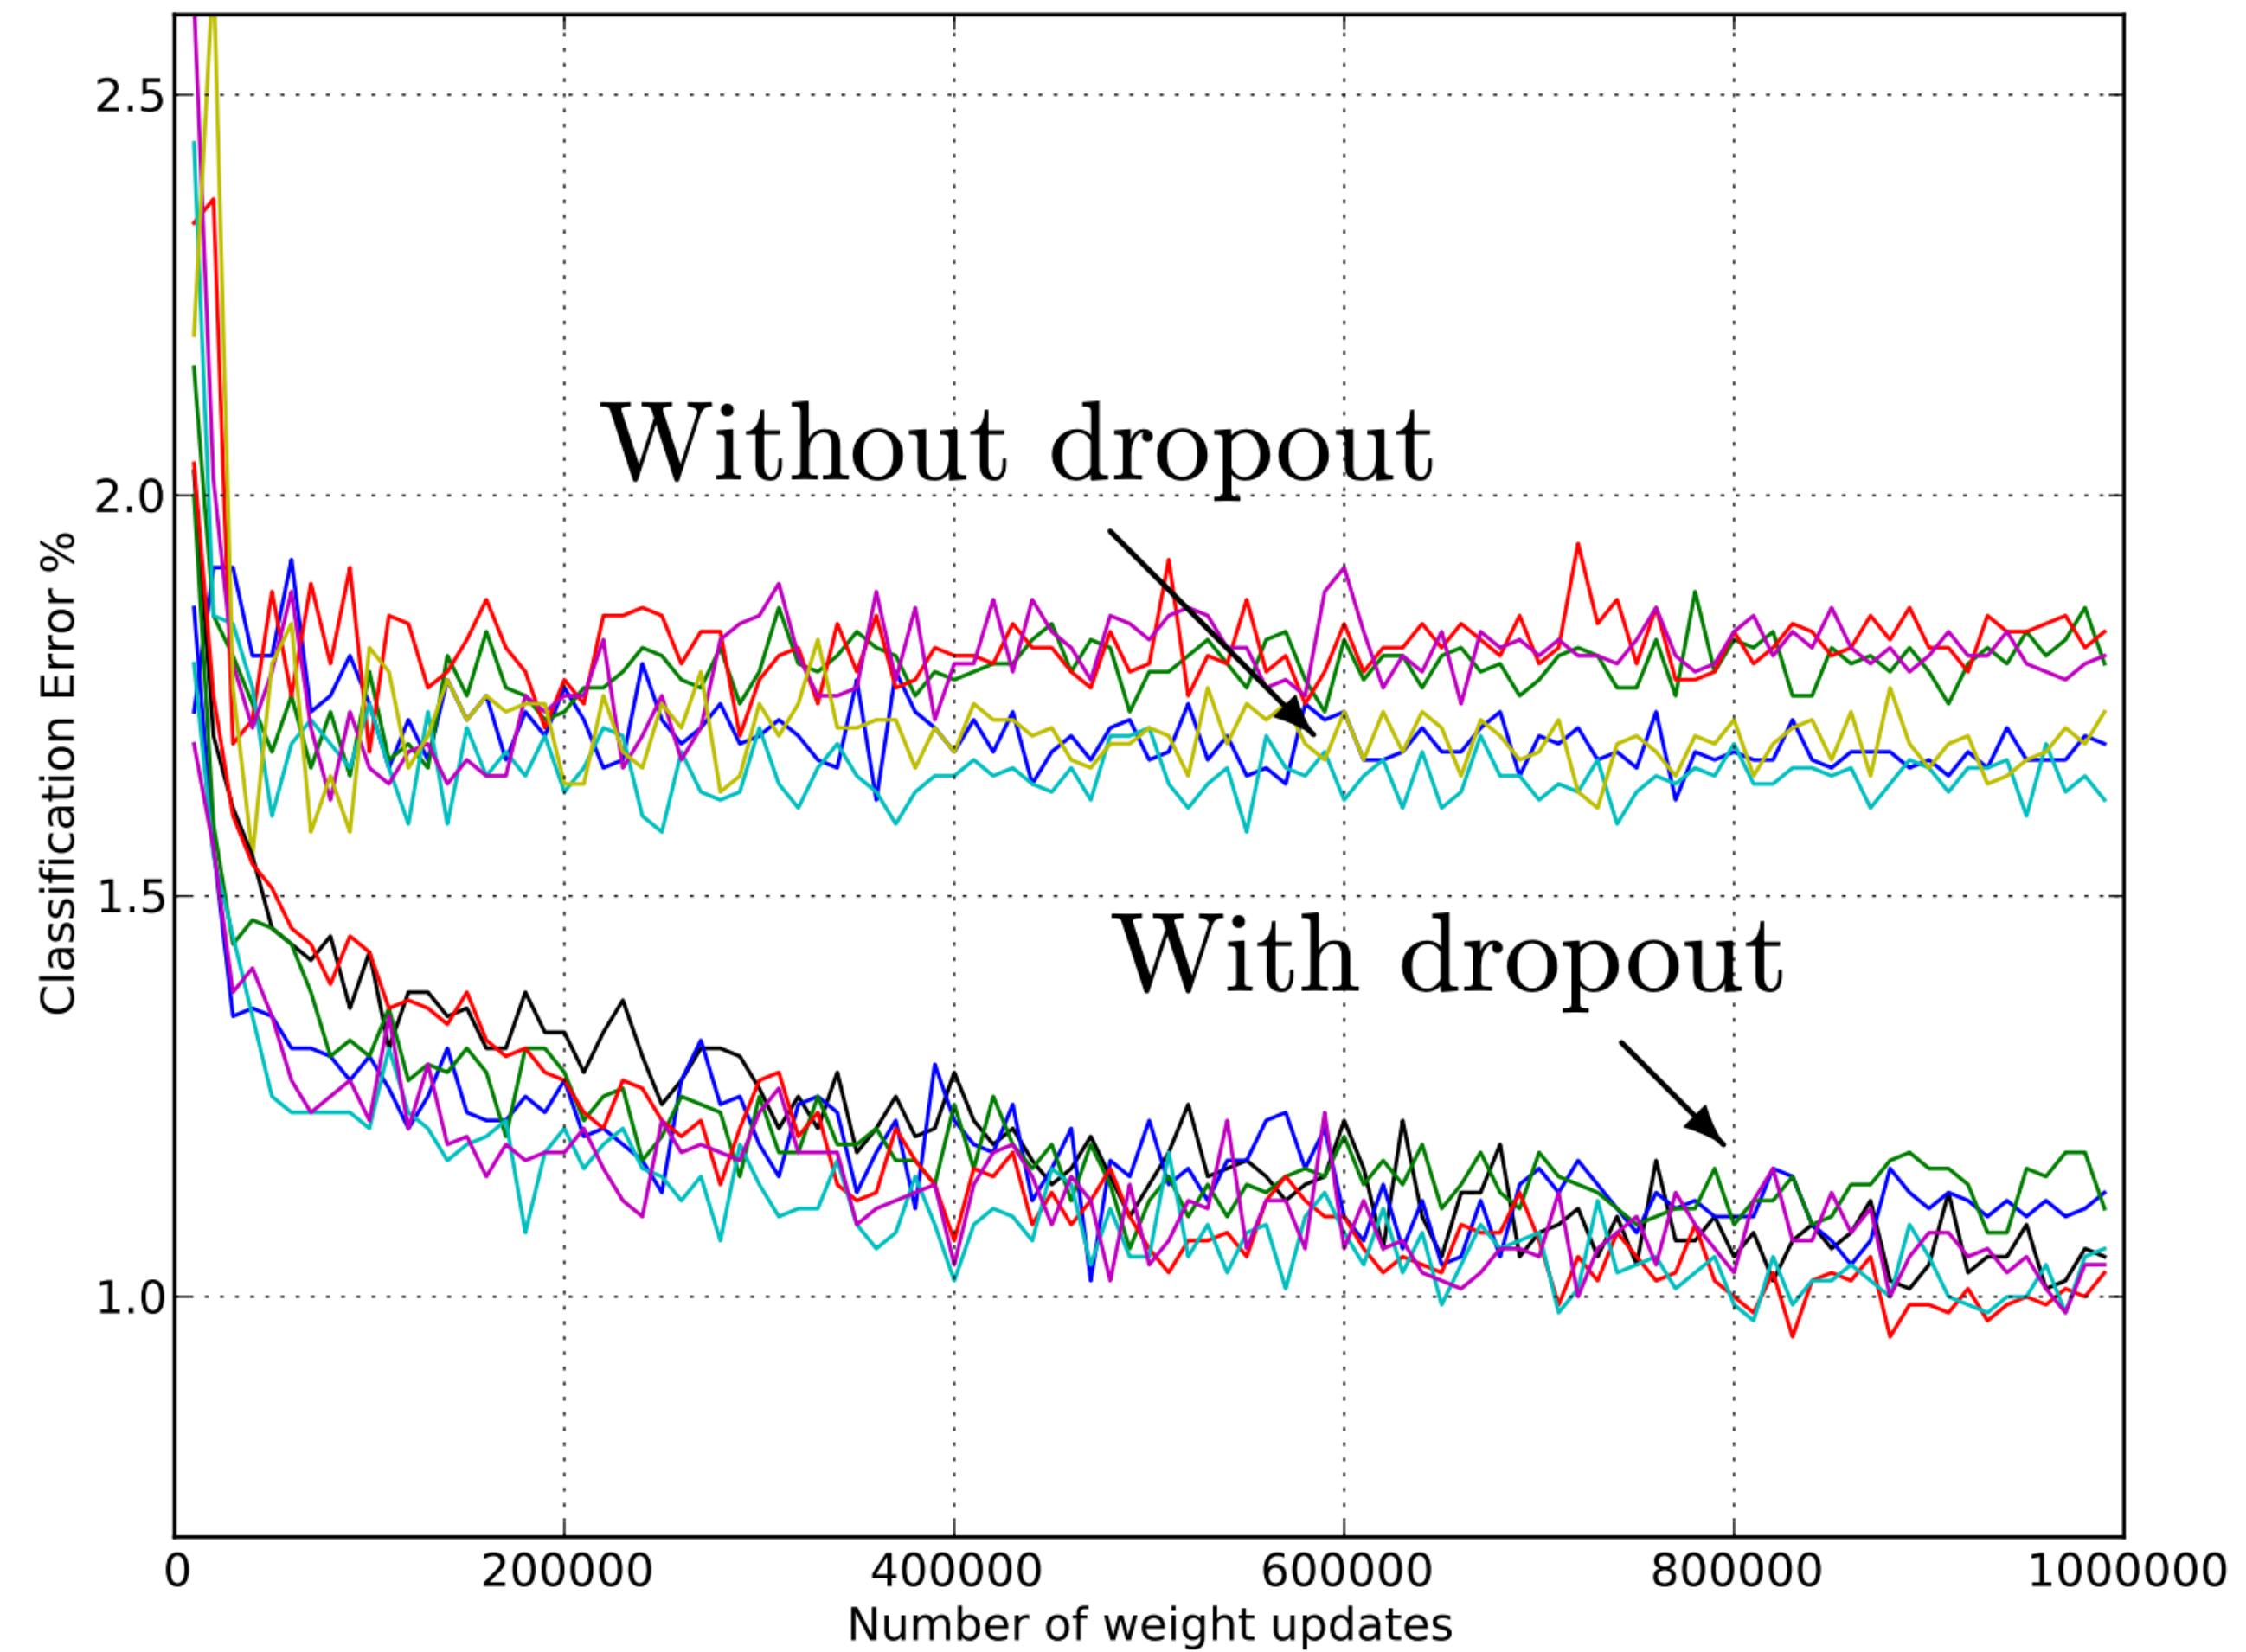

When testing:

- Use all nodes
- Scale each of them by the factor  $p^{(l)}$  to ensure that the expected output (when considering the probability of dropping nodes during training) matches the actual output at test time

Remark: Alternatively, weight rescaling can be implemented during training time by scaling the weights by  $1/p^{(l)}$  after each weight update and no changes are needed in test time - this is how it is implemented in practice

# Dropout: results

- **Setting:** Fully-connected networks of different width and depth on MNIST
- Dropout results in **lower test error**
- However, dropout typically requires more iterations to converge due to increased stochastic noise

# Recap

- Convolutional networks are composed of **sparsely connected convolutional layers** instead of fully-connected linear layers
- The same convolution is applied as a sliding window across all spatial locations
- **Data augmentation** usually results in a significant improvement in the model's generalization performance
- **Weight decay** and **dropout** can further enhance the performance, though typically to a lesser extent
